First Draft: September 20, 2011

This Draft: December 23, 2012

Abstract

How are civilian attitudes toward combatants affected by wartime victimization? Are these effects conditional on which combatant inflicted the harm? We investigate the determinants of wartime civilian attitudes towards combatants using a survey experiment across 204 villages in five Pashtun-dominated provinces of Afghanistan — the heart of the Taliban insurgency. We use endorsement experiments to indirectly elicit truthful answers to sensitive questions about support for different combatants. We demonstrate that civilian attitudes are asymmetric in nature. Harm inflicted by the International Security Assistance Force (ISAF) is met with reduced support for ISAF and increased support for the Taliban, but Taliban-inflicted harm does not translate into greater ISAF support. We combine a multistage sampling design with hierarchical modeling to estimate ISAF and Taliban support at the individual, village, and district levels, permitting a more fine-grained analysis of wartime attitudes than previously possible.

Key Words: civilian casualties; endorsement experiments; intergroup conflict; multilevel modeling; public opinion; sensitive questions

*We thank the Opinion Research Center of Afghanistan (ORCA), and especially Rafiq Kakar, Abdul Nabi Barekzai, Mr. Soor Gul, Zabihullah Usmani, and Mr. Asadi, along with district managers and the 149 enumerators who conducted the survey, for helpful feedback and excellent work under trying conditions. Our program manager, Prakhar Sharma, deserves special thanks. We also thank Will Bullock, Sarah Chayes, Jeff Checkel, Christina Davis, Dan Gingerich, Don Green, Betsy Levy Paluck, and Abbey Steele, along with two APSR Editors and three anonymous reviewers, for helpful comments on an earlier version. The survey instruments, pretest data, or earlier versions of the paper benefited from feedback from seminar participants at the 2010 American Political Science Association annual meeting, George Washington University, Duke University, the University of Pennsylvania, the Ohio State University, University of California—San Diego, the Juan March Institute, the University of British Columbia, Cornell University, Harvard University, Princeton University, and the University of Washington. Financial support for the survey from Yale’s Institute for Social and Policy Studies’s Field Experiment Initiative and the Macmillan Center for International and Area Studies is gratefully acknowledged. Additional support from the Air Force Office of Scientific Research (Lyall; Grant FA9550-09-1-0314) and the National Science Foundation (Imai; Grant SES-0849715) is also acknowledged. This research was approved by Yale’s Human Subjects Committee under IRB protocol #1006006952. An online appendix is available with further details about the survey and analyses.

How does the victimization of civilians affect their support for combatants during wartime? Are the effects of violence on attitudes uniform across warring parties, or are they conditional on *who* inflicted the harm? Despite a widespread belief that modern counterinsurgency hinges on “winning hearts and minds,” scholars have yet to address the theoretical and methodological challenges associated with studying civilian attitudes in wartime settings. Existing theories of civil war violence almost entirely sidestep the question of civilian attitudes. Instead, these theories either assume that attitudes are merely endogenous to battlefield dynamics — and thus not of central theoretical concern — or that civilians treat perpetrators of violence in an undifferentiated fashion. Civilians, existing accounts tacitly assume, are simply guided by a logic of survival that denies them the luxury of taking into consideration prior ethnic or ideological attachments, thus eliminating the need to study wartime attitudes.

We challenge this view by arguing that the effects of violence on civilian attitudes are conditional on combatant identity (Lyall, 2010). We contend that intergroup bias — the systematic tendency to interpret the actions of one’s own in-group in a more favorable light than those of the out-group — should produce robust and observable asymmetries in how combatant actions affect civilian attitudes. Simply put, it is likely that harm by one’s own group carries a different set of implications and effects than victimization by members of an out-group. We anticipate that in-group harm does not lead to either increased support for the out-group or to significant loss of support for in-group combatants. Harm by the out-group, however, is likely to increase out-group antipathy while heightening support for in-group combatants.

To test this argument, we conducted a survey in the very heart of the current Taliban insurgency (Barfield, 2010; Jones, 2009; Crews and Tarzi, 2008; Giustozzi, 2008) that utilizes multiple endorsement experiments to measure civilian attitudes toward the Taliban and the International Security Assistance Force (ISAF) in Afghanistan. We combine a multistage sampling design with multilevel statistical modeling (Bullock, Imai and Shapiro, 2011) to examine attitudes among 2,754 male respondents in 204 villages within 21 districts of five Pashtun-dominated provinces.

Three main findings emerge. First, there is clear evidence that the effects of victimization by ISAF and the Taliban have asymmetrical effects on individual attitudes. Harm inflicted by ISAF is met with reduced support for ISAF and increased support for the Taliban. In contrast, Taliban-inflicted harm does not trans-

late into greater support for ISAF and has only a marginally negative effect on Taliban support. Second, subsequent efforts by each combatant to mitigate the effects of the harm they caused among aggrieved individuals actually appear to be successful, though in ISAF's case this finding rests on a small subset of selected individuals given ISAF's haphazard approach to responding to civilian casualties.¹ Third, we find little support for alternative explanations that privilege prior patterns of violence, the current distribution of territorial control by the combatants, or the role of economic assistance in determining civilian attitudes.

1 Theory and Hypotheses

1.1 Motivation: Rational Peasants, Civilian Agency, and Wartime Attitudes

A near consensus now exists among practitioners around the notion that counterinsurgency wars are decided by the relative success each combatant enjoys in winning popular support from the civilian population (Mao, 1961; Thompson, 1966; Trinquier, 2006; U.S. Army, 2007; Kilcullen, 2009). From the counterinsurgent's perspective, victory is obtained through a combination of service provision, material assistance, information campaigns and, above all, restraint on the use of one's force with the goal of minimizing civilian casualties. From the Vietnam-era Hamlet Evaluation System (HES) to contemporary efforts in Iraq and Afghanistan, winning the "hearts and minds" of the civilian population — or at least an important subset of it — is a central element of counterinsurgency campaigns.

Surprisingly, however, there are few rigorous empirical studies of civilian attitudes toward combatants during wartime (see Beath, Christia and Enikolopov, 2011, for a recent exception). To be sure, this gap is due in part to the logistical and ethical issues that accompany survey research in a wartime setting. Even if surveys could be conducted safely, methodological issues abound: social desirability bias, high refusal rates, and preference falsification may frustrate efforts to obtain reliable answers, especially if sensitive issues such as support for combatants are investigated using direct questions (e.g., DeMaio, 1984; Berinsky, 2004). As a result, one leading scholar has argued we should "bracket [the] question of individual motives and attitudes" (Kalyvas, 2006, 101) in favor of theories that emphasize the more easily observable structure of opportunities and constraints facing civilians in wartime (see also Leites and Wolf,

¹In fact, only 164 of our respondents were approached by ISAF after victimization, while the Taliban approached 535 respondents. See Figure 12 for the full distribution of responses to the harm and approach questions.

1970, 45).

Indeed, the prevailing view of civilians in the civil war literature suggests they are “rational peasants” (Popkin, 1979), that is, utility-maximizing agents driven by the short-term dictates of survival. Without strong ethnic or ideological attachments, civilians seek to minimize their exposure to harm from the combatants while maximizing the benefits offered by combatants, including material assistance and basic security. Based on this consensus, our theories concentrated on explaining which factors drive civilian *behavior*: the relative balance of control exercised by combatants (Leites and Wolf, 1970; Kalyvas, 2006; Kalyvas and Kocher, 2007), competitive service provision (Akerlof and Yellen, 1994; Crost and Johnston, 2010; Berman, Shapiro and Felter, 2011), and relative levels of civilian victimization (Stoll, 1993; Kocher, Pepinsky and Kalyvas, 2011; Condra and Shapiro, 2012, 183–84), to name only three. Prior allegiances, if present at all, are thought to be easily recast in the face of a given mixture of (threatened) punishments and (promised) rewards levied by combatants who aim to exercise control over the civilian population.

Despite privileging different independent variables, these theories converge on the same empirical prediction: civilians should respond symmetrically to combatant actions. Put differently, civilians should be indifferent to which combatant provides material assistance (Collier and Hoeffler 2004, 569; Mampilly 2011, 54–55; Berman, Shapiro and Felter 2011, 776) or victimizes them (Stoll 1993, 20; Kalyvas 2006, 111–19; Condra and Shapiro 2012, 183–84). What matters is the type and amount of aid or violence, not which combatant is responsible for these actions, since civilians cannot afford to discriminate when their survival is at stake. We would therefore expect civilians to respond uniformly to similar assistance provided by foreign and domestic non-governmental organizations, for example. Similarly, these theories expect civilians to provide information to each side equally and routinely, with the choice of which combatant to inform being dictated only by prevailing levels of control or violence.

Yet the empirical findings in these studies are often inconsistent with the baseline expectation of constant causal effects. The effects of aid programs on violence reduction in Afghanistan, for example, appear to hinge on the ethnic composition of a district, not the level of control or prior violence (Beath, Christia and Enikolopov, 2011). Similarly, small-scale aid programs in Iraq have heterogeneous effects across Sunni and non-Sunni dominated districts (Berman, Shapiro and Felter, 2011). In addition, Condra and

Shapiro (2012)’s findings suggest that Sunni districts exhibit markedly different pre- and post-civilian casualty patterns of violence than Shia or mixed districts. In each case, it appears that civilians are responding *asymmetrically*, rather than uniformly, to combatants. If responses are conditional on combatant identities, then we need to theorize how heterogeneity in the effects of aid and violence — variation according to *who* is rewarding or punishing civilians — affects attitudes and subsequent behavior asymmetrically.

Second, these theories rely on indicators of civilian behavior that are observationally equivalent with multiple causal mechanisms. As a result, we are left unable to adjudicate between competing accounts or, more simply, to explain *why* a particular relationship exists. Kalyvas (2006) acknowledges, for example, his central independent variable, the relative distribution of combatant control, generates its effects via at least six different mechanisms, three of them attitudinal in nature (124–32). Observational data cannot tease apart these different mechanisms; only by directly measuring attitudes can the relative influence of each mechanism be determined.² Getting the mechanisms right also has important policy implications: it matters whether civilians are providing tips to insurgents because they fear punishment for non-cooperation or if they genuinely support the rebel cause since the policy response is likely to be different even if rebel control is constant in these scenarios.

1.2 Why Identity Matters: Intergroup Bias and Support for Combatants

We argue that wartime attitudes are shaped by intergroup biases that create durable expectations about the responsibility and blame for combatant actions toward the civilian population. These biases lead civilians to condition their interpretation of events on the perpetrator’s identity (Lyall, 2010). As a result, we expect that support for combatants will depend on the combatant’s identity, as will the effects of actions taken by the combatants.

We define intergroup bias as the systematic tendency by individuals to evaluate one’s own membership group (the “in-group”) more favorably than a group one does not belong to (the “out-group”) (Tajfel, 1970; Tajfel and Turner, 1979; Hewstone, Rubin and Willis, 2002, p. 576).³ Positive actions by one’s own

²The same criticism holds true for work on civilian victimization, where mechanisms purporting to explain civilian behavior have proliferated but research designs capable of testing them have not.

³The literature on social categorization theory, and related fields such as prejudice, discrimination and biased assimilation theory, is enormous. For overviews, see Tajfel (2010), Hewstone, Rubin and Willis (2002), Lord, Ross and Lepper (1979), and Paluck and Green (2009).

in-group are therefore viewed as arising from the innate disposition of in-group members while similar actions by the out-group are interpreted as situational in nature: the out-group was compelled by the situation to undertake a positive act, whereas the in-group did so because of its inherent nature. Negative actions by an in-group, by contrast, are understood as situational in nature (“forced to be bad”), while negative actions by the out-group confirm biases about the out-group and its members as bad actors.

Laboratory experiments have shown that intergroup bias is especially prevalent in situations where the out-group possesses a significant power advantage and members of the in-group feel threatened by the out-group (Brewer, 1999; Esses et al., 2001; Hewstone, Rubin and Willis, 2002, 585-86). Such conditions characterize counterinsurgency wars, in which members of a group are challenging a much stronger out-group such as a national government or external occupier in a bid for independence, autonomy, or state capture.⁴ The potentially high degree of risk assumed by individuals for (non-)participation in an insurgency means that intergroup biases help reduce uncertainty in confusing wartime conditions.

One potential basis for in-group identification is ethnicity.⁵ Ethnicity can perform two functions under wartime conditions. First, it acts as a shorthand or “social radar” (Hale, 2008, 34) that allows forward-looking individuals to anticipate the nature of in- and out-group actions based on prior interactions or information about ethnic types. In particular, ethnicity can convey information about often unobservable characteristics about other relevant actors — especially soldiers and rebels — such as the credibility of their threats and assurances for (non-)compliance. Biases about (non-)coethnics can thus be drawn on to facilitate wartime risk management by allowing individuals to quickly attach probabilities, if only crudely, to the expected (re)actions of combatants (Lyll, 2010, 15).

Second, and central to our argument, group membership also moderates beliefs about responsibility and blame for *past* actions toward the individual and her group. Viewed through the lens of intergroup bias, individuals are more likely to punish out-groups for transgressions, simply confirming biases about the out-group’s disposition. Harm inflicted by the in-group, however, carries a different meaning: victimized individuals, and the community at large, may be more forgiving, since such acts are justified by appeal to

⁴This discussion presumes a single in/out-group cleavage, but this could be complicated by introducing multiple out-groups or in-group fissures (on this point, see below).

⁵*Ethnicity* is defined as an identity category in which descent-based attributes are necessary for membership (Chandra and Wilkinson, 2008, 517).

Action	Actor	Expected Effect on Individual's Support for	
		Out-Group	In-Group
Negative	Out-Group	Negative	Positive
Negative	In-Group	Neutral	Neutral/Weak Positive

Table 1: Home Team Discount: The Asymmetry of Combatant Support in Civil War.

extenuating circumstances that forced the in-group's hand. This bias helps explain why external occupiers are often blamed by victimized individuals for harm that was actually inflicted by the rebels themselves.

This discussion generates several conditional hypotheses, which are characterized by two types of asymmetry. Table 1 summarizes these hypotheses. First, we anticipate that harm inflicted by the out-group will be associated with a sharply negative effect on civilian attitudes toward the out-group (Hypothesis 1) and a correspondingly large rally effect for insurgents drawn from the in-group (Hypothesis 2). Taking Hypotheses 1 and 2 together, we should observe a clear asymmetry of effect on attitudes that is conditional on the joint identities of the perpetrator and victim(s).

Second, the in-group's victimization of civilians will not result in a transfer of support to the out-group (Hypothesis 3) but will instead generate only a neutral effect on out-group support. We may observe a modest negative effect on in-group support (Hypothesis 4), though this should be substantially smaller than the negative effect on out-group support after civilian victimization. Here we observe a second, more subtle, asymmetry: Unlike out-group victimization, which leads to support for in-group, in-group victimization does not lead to a corresponding increase for the out-group. We term this the "home team discount:" insurgents may be less constrained in their abuse of their fellow in-group members since such actions do not lead to a corresponding positive effect on support for the out-group.⁶

This theory of intergroup bias is underpinned by a particular view of how *private* attitudes condition subsequent behavior. We draw on a distinction developed by social psychologists between *public* and *private* attitudes, because the two are thought to predict different types of behavior (Dovidio et al., 1997, 519–20). Individuals may express socially desirable attitudes publicly, for example, as a means of avoiding sanction by other community members. These public attitudes are shaped by an individual's surroundings and are typically expressed out of a desire to conform even though individuals privately hold alternative views. In a wartime context, public attitudes are likely predictors of events such as participation in public

⁶We anticipate that similar asymmetry should result when individuals judge positive actions, i.e., giving aid, but a proper test of this conjecture is beyond the scope of this paper.

demonstrations, openly siding with an occupying force (i.e. in a militia), or service provision on behalf of a combatant. These events share a public aspect that enables external observers to police revealed attitudes by observing behavior, administering sanctions if behaviors are not congruent with desired attitudes.

Private attitudes, by contrast, are personal, conscious views shaped primarily by one's own moral standards and ideals. These attitudes reside with the individual alone and the in-group holds an incomplete ability to monitor them sufficiently to enforce total attitudinal conformity. In wartime settings, private attitudes would predict participation in more clandestine activities, including providing information to combatants through anonymous tips and secret collaboration. Private attitudes are thus likely behind decisions about taking up arms, especially against the counterinsurgent. Such efforts are secretive by nature, regardless of their target: insurgents take special precautions to conceal their identities while also seeking to avoid information leaks or defection that could destroy the group itself.

This emphasis on private attitudes suggests that violence affects support for combatants through personal victimization rather than indirect knowledge of the victimization of others. Thus, we hypothesize that as we move from an individual's direct experience with the combatants to indirect experiences shared by other in-group members the effects of victimization on combatant support should attenuate. Put differently, the magnitude of the action's effect, but not its direction, should diminish as we move from direct experiences to indirect ones provided by secondhand accounts, combatant propaganda, or rumors (Hypothesis 5).

Simply put, we anticipate that the effects of combatant violence on civilian attitudes are asymmetrical, not uniform. Violence by the out-group toward civilians should have negative effects on support for that group (normally the counterinsurgent or national government) while having a positive effect on support for the in-group. In-group violence, by contrast, should result in only a modest negative effect on in-group support (if any effect is recorded) and should not yield a transfer of support to the out-group.

2 The Survey

We adopt a survey methodology that employs a battery of indirect endorsement experiments to measure attitudes. Endorsement experiments are especially apt for environments such as Afghanistan, where

concerns about safety, social desirability bias, and non-random refusals to participate are present in spades (Blair et al., Forthcoming; Bullock, Imai and Shapiro, 2011). In addition, there are Afghanistan-specific reasons for concern. First, ISAF, along with other organizations, have spent billions of dollars over the past decade seeking to win “hearts and minds.” This situation creates and reinforces incentives to provide answers perceived to be acceptable to ISAF, especially if individuals believe future receipt of aid is conditional on current responses. Moreover, for cultural reasons individuals are typically surveyed in public settings. We recorded an average of two additional individuals present at each survey session, excluding the respondent and enumerator.⁷ Finally, our survey firm negotiated access to villages with local elders, *arbaki* (militia) commanders, and Taliban leaders. In such situations, indirect questions are preferable because they yield a higher rate of acceptance among these gatekeepers, thus avoiding biases in the choice of interview locations.

2.1 The Endorsement Experiment

The mechanics of a survey endorsement experiment are straightforward. Randomly selected respondents are assigned to a treatment group and asked to express their opinion toward a policy endorsed by a specific actor whose support level we wish to measure (here, ISAF and the Taliban). These responses are then contrasted with those from a control group of respondents that answered an identical question without the endorsement. Higher levels of enthusiasm for a policy with an endorsement relative to those without it are viewed as evidence of support for the endorsing actor. Since each respondent is assigned only one condition for any endorsement experiment, it is impossible for enumerators or others to compare support levels across different conditions for any individual respondent.

Drawing on electronic and print media, as well as focus groups and two pretest surveys conducted in sampled districts, we identified four policies with the properties desired for an endorsement experiment. Successful endorsement experiments share four properties (Bullock, Imai and Shapiro, 2011). First, selected initiatives should be in the same policy space so that they can be combined for statistical analysis. We select policies that are all related to domestic policy reforms: prison reform, direct election of district

⁷Despite the group setting, only one individual’s answers were recorded, and enumerators were trained not to interview these passersby to avoid creating a convenience sample.

councils, a reform of the Independent Election Committee, and the strengthening of anti-corruption policies. Second, these initiatives should be well known by individuals to minimize “Don’t Know” responses and to differentiate support for an endorser from learning about a policy from the endorsement itself. In the survey, only 4.5% of respondents replied “Don’t Know,” while refusal rates were low in all provinces. Third, these initiatives should actually be endorsed by the particular actors in question so that the questions are realistic and respondents take them seriously (Barabas and Jerit, 2010).⁸ Finally, a wide range of views was held by the general public about these initiatives, enabling us to detect support for endorsers without suffering from ceiling and floor effects.

Here, we reproduce one endorsement question, calling for reform of Afghanistan’s notoriously corrupt prison system, below. Appendix A.1 details the remaining three endorsement experiments, and describes the motivation for each.

- **CONTROL CONDITION:** A recent proposal calls for the sweeping reform of the Afghan prison system, including the construction of new prisons in every district to help alleviate overcrowding in existing facilities. Though expensive, new programs for inmates would also be offered, and new judges and prosecutors would be trained. How do you feel about this proposal?
- **TREATMENT CONDITIONS:** A recent proposal by the Taliban [or foreign forces] calls for the sweeping reform of the Afghan prison system, including the construction of new prisons in every district to help alleviate overcrowding in existing facilities. Though expensive, new programs for inmates would also be offered, and new judges and prosecutors would be trained. How do you feel about this proposal?

Plagued by allegations of widespread overcrowding and systematic torture, among other human rights abuses (Human Rights First, 2011), the Afghan prison system has been publicly criticized by ISAF, the Taliban, and outside observers alike. When polled, only 48% of Afghans claim to place any faith in the Afghan prison system (The Asia Foundation, 2010). As a result, both ISAF and the Taliban have at various occasions offered remarkably similar reform programs (Nixon, 2011; International Crisis Group, 2008).⁹

As for all four endorsement questions, respondents were asked to assess their level of support for each proposal on a five-point scale: “I strongly agree with this proposal”; “I somewhat agree with this proposal”; “I am indifferent to this proposal”; “I disagree with this proposal”; and “I strongly disagree

⁸Deception is also avoided with this approach.

⁹After consultation with our field teams as well as our survey pretests, we used the term “foreign forces” rather than “ISAF” since this is the most common term used by Afghans. The term “ISAF,” by contrast, was unfamiliar to nearly all respondents.

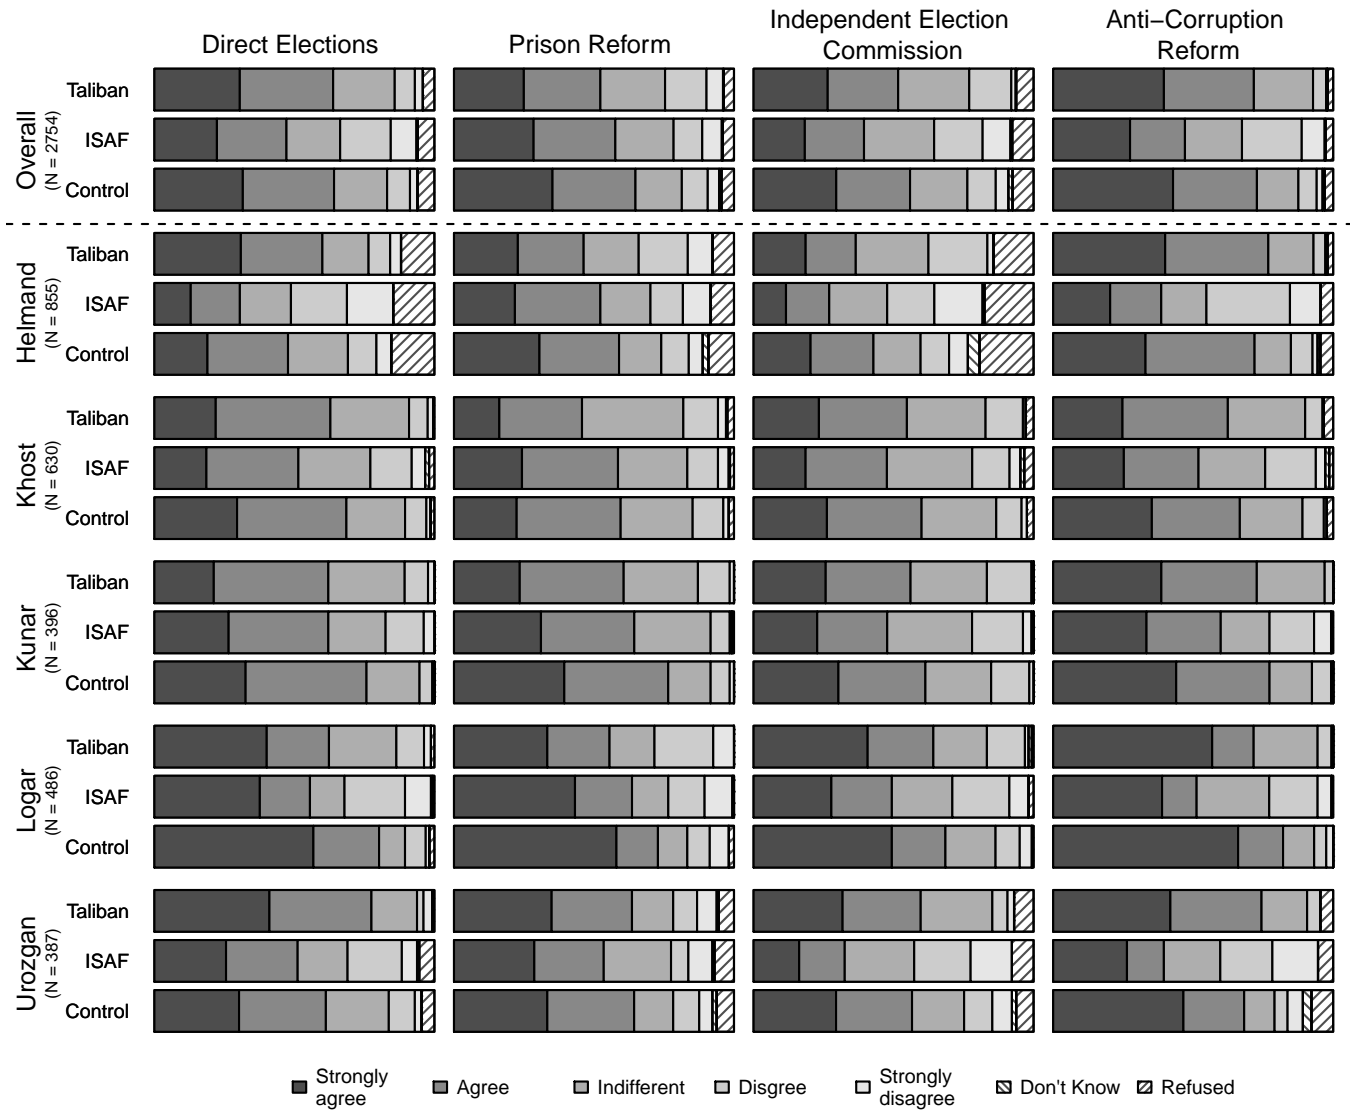

Figure 1: Overall and Within-Province Distribution of Responses from the Endorsement Experiment. Plots depict the distribution of responses to four policy questions (columns) across three groups (Taliban/ISAF endorsement groups and control group) for the overall sample (top row) and each province (bottom five rows). Sample sizes are also shown.

with this proposal.” Respondents were also permitted to answer “Don’t Know” or “Refuse to Answer.”

Figure 1 displays the overall (top row) and provincial distributions of responses to the four endorsement questions. Three patterns are worth noting. First, there is substantial heterogeneity of inter-province support for these policies, even independent of particular endorsements. This is encouraging since it suggests that the questions, taken separately or together, possess strong discriminatory power. Compare higher support for prison reform in Logar, for example, with Khost, or anti-corruption efforts in Logar with Helmand. Second, support differs substantially across Taliban and ISAF endorsements. In some provinces including the Taliban stronghold of Helmand or the warlord-controlled Uruzgan, support for

Taliban endorsed policies is far higher than ISAF endorsed policies. In fewer cases, notably in the key battleground province of Kunar, ISAF endorsement translates into higher support for at least two proposals. To further validate whether the endorsement experiments are measuring the support for the Taliban and ISAF, Appendix A.2 presents a detailed descriptive analysis, which argues that the patterns we observe across provinces and districts are consistent with conditions in each province at the time of the survey.

2.2 Sampling Design and Target Population

Our survey experiment was conducted between 18 January and 3 February 2011 in five provinces of Afghanistan.¹⁰ We chose to concentrate on Pashtun-majority areas rather than a nationwide sample for three reasons. First, estimation at the village and district level requires a sufficient number of individual respondents and selected villages, respectively, making a nationwide sample prohibitively expensive if we scaled up with the same level of coverage. Second, these areas are not only substantively important — they encompass the Taliban “heartland,” and are considered the battleground provinces of the Afghan war — but are also areas where intergroup bias between Pashtuns and ISAF should be present. Third, these areas have experienced with both ISAF- and Taliban-initiated violence. Indeed, they represent the high end of the distribution of violence.

We devised a multistage sampling design to generate estimates of support for combatants at the individual, village, and district levels. First, five provinces — Helmand, Khost, Kunar, Logar, and Uruzgan — were randomly selected from the 13 Pashtun-majority provinces.¹¹ Next, we randomly selected one-third of each province’s districts for a total of 21 selected districts. Third, villages were randomly sampled from these districts with the restriction that at least 10% of each district’s villages had to be selected, yielding 204 villages. Households were then chosen within these villages using the random walk method. Finally, male respondents aged 16 years and older were randomly selected from these households using a Kish grid. We surveyed nine respondents from villages with populations below the mean of sampled villages

¹⁰The survey was implemented by the Opinion Research Center of Afghanistan (ORCA), an Afghan-owned firm that recruits all of its enumerators locally. Two pretests were also run, from 25 September to 5 October and 22 November to 5 December 2010, to pilot different endorsement policies, to assess sensitivity to question order (none was found), and to obtain feedback from enumerators about respondent reactions and security issues. Taken together, the pretests had 600 respondents in 40 villages from 10 districts within our sampling frame. These villages were later removed from our sampling frame to avoid contaminating results.

¹¹The remaining eight provinces are Ghazni, Kandahar, Laghman, Nangarhar, Paktia, Paktika, Wardak, and Zabul.

							Violent events initiated by	
Provinces	Districts		Villages		Individuals		Taliban	ISAF
	total	sample	total	sample	total	sample		
Helmand	13	5	1,578	61	1,411,506	855	11,806	2,074
Khost	13	5	880	45	754,262	630	779	257
Kunar	15	5	818	30	548,199	396	1,015	166
Logar	7	3	641	40	384,417	486	681	137
Urozgan	5	3	514	28	324,100	387	849	314
Total	53	21	4,431	204	3,422,484	2,754	15,130	2,948
8 non-sampled Pashtun provinces	112	0	10,383	0	6,156,571	0	10,007	2,135
Other 21 provinces	21	233	0	20,786	0	14,903,729	0	3,829
							1,225	

Table 2: Multistage Sampling Design Overview: First, five provinces shown in this table were randomly sampled from a total of 13 provinces with a Pashtun majority. Second, districts were randomly chosen within these districts. Third, villages were then randomly sampled from within selected districts. Fourth, households were randomly selected within each of the selected villages. Finally, one male respondent 16 years or older was randomly sampled within each of the selected households. The table also displays the number of Taliban- and ISAF-initiated violent events during one year prior to the survey (from 18 January 18 2010 to 17 January 2011) inflicted at the provincial level.

(about 680 individuals) and 18 in villages with above-mean populations. Table 2 summarizes our sampling design and the realized sample.

We obtained an 89% participation rate (2,754 out of 3,097 attempts). Figure 2 presents the distributions of basic demographic variables for our sample of 2,754 respondents. Our average respondent was a 32 year old Pashtun male who was likely married (77% answered yes), possibly employed (only 58% reported holding a job, with the most frequent occupation being “farmer”), and earning between US \$1.40 and \$6.97 a day. Respondents typically had little or no government-provided schooling, and on average had only six months of madrassa religious schooling. In keeping with the high poverty rates of the sample area, respondents on average had less than 90 minutes of electricity a day. Less than half (48%) possessed cellphones, while nearly all (90%) owned a radio, the principal means of obtaining information. Ethnic minorities, mostly Tajiks, made up 7% of the respondents and had comparatively higher rates of education and employment.

Since the vast majority of Afghans live in small rural settlements, we avoided sampling from large urban centers such as district capitals. Our villages thus range from 20 to 2509 inhabitants (mean: 680 individuals). We also made the difficult decision to include only male respondents given the cultural and logistical challenges of interviewing women in these violent and deeply conservative areas. Our protocol

Figure 2: Distribution of Demographic Characteristics. Bar plots indicate the number of respondents in each category for demographic variables. Dashed lines represent median values.

included a special consent form for those aged 16 – 18 years. We elected to include these individuals since Afghanistan’s median age is only 18, a fact typically overlooked by existing surveys of public opinion.

Of the original 204 villages, only four proved inaccessible due to a combination of Taliban hostility, the presence of criminal elements and, in two cases, the inability of the enumerators to locate the selected village.¹² In all cases, village elders, who may have been members of the Taliban, were first approached by ORCA district supervisors with the relevant connections to describe the survey and to receive assurances of enumerator safety. Despite our extraordinary level of access to Taliban-controlled areas, a testament to ORCA’s connections as well as its decision to hire locals enumerators, we nonetheless experienced myriad delays and logistical challenges. These included movement restrictions due to open war-fighting (especially in Helmand); Taliban and militia roadblocks (typically appearing after 2pm in most of our districts); and attempted highway robbery. In one case, a clean-shaven enumerator was pulled from his car in Kunar where, along with other motorists, his face was blackened with motor oil by local Taliban to signify his “sinfulness.”¹³ Our most serious incident involved a district manager in Uruzgan, who was wounded by a roadside improvised explosive device (IED) the day after placing the last bundle of completed surveys on a fruit truck (our method of returning surveys to Kabul).

2.3 Measuring Exposure to Violence

Table 2 outlines just how violent these provinces have been using two different datasets. The number of attacks initiated by the Taliban and ISAF from 18 January 2010 to 17 January 2011 was extracted from

¹²Each village was matched with a similar replacement that the enumerators could select if conditions warranted. These replacements were used in the four cases mentioned.

¹³In a sign of how routine this practice has become, roadside shopkeepers had set up a thriving business charging these unlucky individuals a 100 Afghanis “per face” charge for soap and water.

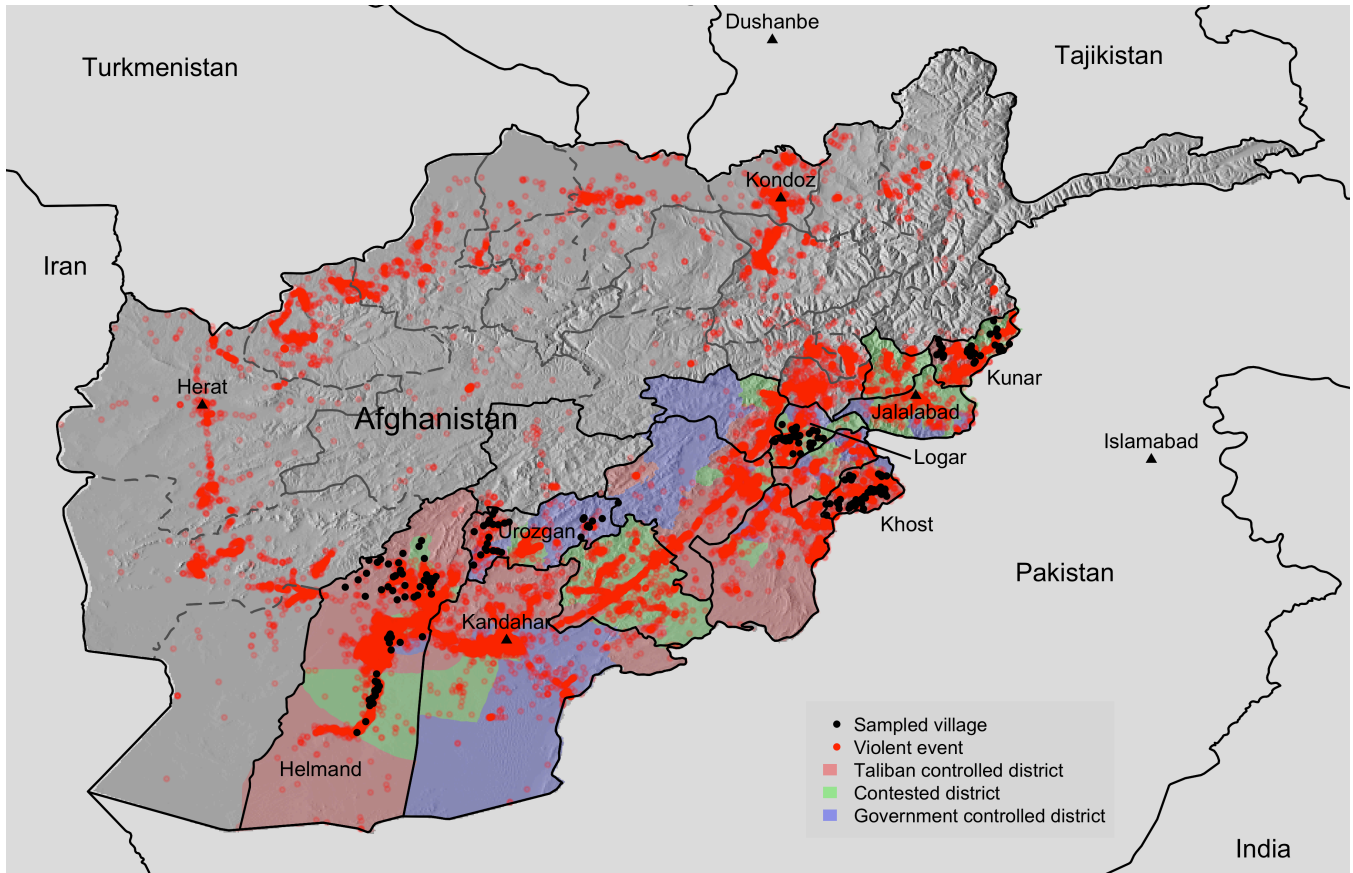

Figure 3: Sampled Villages. Black dots represent randomly sampled villages within five Pashtun-dominated provinces. Red dots represent Taliban- or ISAF-initiated violence in 2010. Three colors are used to distinguish Taliban-controlled (red), Government-controlled (blue), or contested (green) districts.

ISAF’s Combined Information Data Network Exchange, which records the date, location, and type of event from 17 specific categories.¹⁴ These data show that the sampled provinces have experienced variable levels of violence but, on average, are considerably more violent than other non-Pashtun provinces.

Figure 3 illustrates this pattern by overlaying the location of sampled villages (as black dots) on the distribution of Taliban and ISAF violence (as red dots) during 2010. Two spatial patterns emerge immediately. First, while some of our surveyed villages are within extremely violent areas, other sites experienced relatively few attacks nearby, giving rise to considerable heterogeneity in the level and type of harm experienced by respondents. Second, we overlay the spatial distribution of relative control by combatants, as measured by ISAF, at the district level. Nine of the 21 districts are defined as under Taliban control (red areas), while another nine were coded as “contested” (green areas). Only three districts in our sample are

¹⁴The specific event categories: ISAF (Cache Found, Direct Fire, Escalation of Force, and Search and Attack) and Taliban (Assassination, Attack, Direct Fire, IED Explosion, IED False, IED Founded/Cleared, IED Hoax, Indirect Fire, Mine Found, Mine Strike, SAFIRE, Security Breach, and Unexploded Ordinance).

thus considered under central government or pro-ISAF local control (blue areas). These data underscore both the difficulties of research in these areas as well as the fact that, for nearly all respondents, experience with harm at the hands of ISAF or the Taliban (or both) is not an abstract notion but a realistic possibility—and, for many, a reality. In Appendix A.3, we demonstrate that though these provinces are more violent than non-Pashtun provinces, the sampled villages exhibit violence levels similar to non-sampled villages in these districts. We also show that sampled villages are similar to non-sampled villages on other substantively important dimensions. As expected with multi-stage sampling, in-sample balance at the district and province level is slightly worse, given the small samples of districts (21) and provinces (5).

We measure our central explanatory variable, exposure to harm at the hands of ISAF or the Taliban, with several questions. We distinguish between two models of harm: direct exposure, in which an individual or his family are directly affected in the past year; and indirect exposure, in which individuals are asked about their awareness of ISAF- or Taliban-inflicted harm within their *manteqa* (area) over the same time period. These self-reports, elicited prior to the endorsement experiments, were preceded by a script that defined “harm” as both physical injury and property damage. These questions and detailed descriptive analyses appear in Appendix A.4.

Our respondents reported a staggering degree of exposure to ISAF and Taliban violence. Some 37% of respondents indicated that they had personally experienced victimization by ISAF, while a similar 33% acknowledged Taliban victimization (left corner plot in Figure 12(a) in Appendix A.4). Nearly 70% of respondents had heard of ISAF harming civilians in their *manteqa*, while about 40% had similarly heard of Taliban-inflicted harm in their area over the past year (left corner plot in Figure 12(b)).

These self-reported measures were followed by questions about whether the individual had directly experienced or was indirectly aware of the efforts by the responsible combatant to make amends for harm inflicted. These questions are designed to test whether intergroup biases are irretrievably fixed or, instead, there remains the possibility of softening, if only partially, these biases in a wartime setting. We are therefore able to classify individual experiences by exposure to harm (yes/no), by combatant, and whether the individuals were directly approached by the combatants following victimization or had heard of such efforts within their *manteqa*.

To be approached by ISAF signifies that an individual or family received a one-time *solatia* payment, typically around \$2,500, that absolved ISAF of criminal liability for civilian casualties or property damage.¹⁵ By contrast, to be approached by the Taliban signifies that the aggrieved party received a funeral oration by the Taliban extolling the virtues of the fallen individual(s) as well as modest monthly payments or basic staples such as kerosene or foodstuffs.

Yet can we rely on these self-reports, especially those obtained via direct questions? At least two objections might be raised. First, we may be concerned that questions of wartime harm are simply too sensitive to elicit truthful answers. This, too, was our initial concern, but one subsequently mitigated when enumerators reported that respondents, far from being reticent about sharing their experiences, were only too eager to describe them. In fact, the combined rate of “Don’t Know” and “Refuse to Answer” for these questions was only 2% for Taliban and 1% for ISAF-inflicted harm questions.¹⁶

Second, there may be endogeneity between the certain covariates — for example, the level of combatant control, or an individual’s socioeconomic and cultural attributes — and survey responses. Individuals did report a much greater (second-hand) awareness of ISAF victimization than Taliban misdeeds, for example. This may suggest a greater willingness to speak openly about ISAF, especially in the Taliban-controlled districts that represent 43% of our sample. Coethnic bias itself may also skew these self-reports: Pashtuns could conceivably be more likely to report ISAF victimization than harm by the almost-exclusively Pashtun Taliban.

Without dismissing the dangers of endogeneity, there are reasons to believe such concerns may be muted. First, minimal non-response rates were recorded; respondents clearly were not hiding their answers behind appeals to “Don’t Know” and “Refuse to Answer.” Second, almost identical levels of victimization were recorded at the hands of ISAF and the Taliban. Third, substantial variation exists within Taliban-controlled and contested districts (and villages), suggesting that a heavy Taliban presence does not necessarily dictate pro-Taliban answers. Fourth, the large discrepancy between indirect exposure to

¹⁵In 2010, the US spent \$4.44 million on 1114 condolence and battle damage payments. For our sample, Helmand had the greatest share of payments ($N = 518$, \$2.8 million), followed by Kunar ($N = 48$, \$129,000), Khost ($N = 40$, \$66,197), Urozgan ($N = 15$, \$76,000), and Logar ($N = 12$, \$44,000). The mean disbursement was \$3,982, though payment per individual was far lower.

¹⁶Yale’s IRB ruled out collecting data on the specific nature of harm inflicted since these details could, in theory, be used to identify individuals in a given village if these data were compromised. Note that the emphasis here on physical and property damage may underestimate other forms of intimidation such as Taliban “night letters.”

ISAF and Taliban victimization is likely due to the Taliban's own impressive and far-reaching information campaign. Unlike ISAF, the Taliban is adept at disseminating news of ISAF-inflicted civilian casualties (real or imagined) via cellphones videos and SMS as well as routine visits to villages. The efforts of ISAF lack the reach of those of the Taliban and remain largely confined to urban centers and traditional media.

Finally, to complement respondent self-reports, we calculated the number of attacks initiated by the Taliban and ISAF occurring in or near each village. To be consistent with our survey questions, we count only the attacks that occurred within a five kilometer radius of each village during one year prior to the survey. This event data offers an extraordinarily fine-grained measure of violence that can act as an important, if limited, alternative measure to our self-reported measures of exposure to harm. Intriguingly, we find little correlation between these individual self-reports and ISAF's own dataset of violent events. We constructed measures of violence using the number of Taliban and ISAF-initiated events during the year prior to the survey at different radii around these villages and found little correlation.¹⁷ Moreover, there is almost no correlation between these self-reports and ISAF's own civilian casualty data. ISAF's data suggest that the Taliban are responsible for inflicting 89% of incidents involving the death or wounding of civilians in 2010 (or, by UNAMA's estimate, 83% of civilian deaths). By contrast, our self-report data reveal a much more even distribution of harm inflicted, with a slightly larger proportion of respondents reporting victimization at the hands of ISAF compared to the Taliban.

Several factors may account for this discrepancy. First, the two measures operationalize harm differently. ISAF's data focuses solely on deaths and wounded, while our self-reports measure both physical harm and property damage. The latter category, which ISAF does not collect systematically, is critical because it represents a far more frequent occurrence than the rare mass-casualty events that command media attention. Second, ISAF's coding rules for assigning responsibility for a particular event rely on objective indicators (e.g. if a Taliban-placed IED kills civilians, then the Taliban is assigned responsibility for the event) while the population may not be making the same calculation (e.g. ISAF is blamed for IED-conflicted casualties since ISAF's presence made the IED likely). Finally, these self-reports measure

¹⁷The correlations between mean self-reported harm to the individual or family and to others in the respondent's *mantega* area and the count of the number of violent events at 1-km, 5-km, and 10-km radii from villages are less than .1 in absolute value with few exceptions. The only strong relationship with violent events is with respondents' perceptions of harm inflicted to other individuals in their province. Those responses are strongly correlated (between .2 and .25) with violent events within 5-km and 10-km of villages.

individual-level exposure, while ISAF’s event data in present form can only be pegged to the village level. For these reasons, we believe that our self-reports offer a more comprehensive measure of harm inflicted than ISAF’s own data.

3 Statistical Modeling

Since all four questions occupy the same policy space, we employ the methodology developed by Bullock, Imai and Shapiro (2011) to combine responses from the four endorsement experiment questions to uncover the underlying latent levels of support for each combatant. We exploit the multistage sampling design of our survey experiment and construct a multilevel model where each level directly corresponds to each stage of sampling. Under this model, for example, a village-level parameter is assumed to be randomly drawn from a distribution defined at the district level in which the village is situated. This corresponds to the sampling process, in which villages are randomly selected from the population of villages within each of the sampled districts. Our multilevel modeling approach is thus justified by the sampling design and allows us to estimate (via partial pooling) support levels of the Taliban and ISAF and their difference at all four levels – individuals, villages, districts, and provinces – providing a wealth of information about the spatial distribution of support. Finally, our model can also accommodate predictors at each of the four levels including individual-level survey measures and village-level violence data.¹⁸ The model also allows for spatial correlation at the village, district, and province levels through the introduction of random effects at each level.

We now formally define our statistical model. Let i index survey respondents in our sample ($N = 2,754$). In the endorsement experiment, each respondent is randomly assigned to one of the three conditions with equal probabilities — Taliban endorsement, ISAF endorsement, and no endorsement (control condition). We use T_i to denote this randomized “treatment” assignment, which takes one of the three values, i.e., $2 = \text{Taliban}$, $1 = \text{ISAF}$, and $0 = \text{Control}$. Now, respondent i ’s answer to the j th policy question is represented by Y_{ij} for $j = 1, \dots, 4$ and is recorded as the 5-category ordinal response variable, $5 = \text{Strongly agree}$, $4 = \text{Agree}$, $3 = \text{Indifferent}$, $2 = \text{Disagree}$, and $1 = \text{Strongly Disagree}$. Following Bullock,

¹⁸The standard regression approach with “cluster robust standard error” cannot incorporate the sampling design into the estimation and also is not suited for data with a complex correlation structure.

Imai and Shapiro (2011), we partially pool all policy questions in order to identify the common underlying pattern across all questions rather than idiosyncratic noise associated with a particular question.

First, the individual level is based on the ordered probit item response model: $\Pr(Y_{ij} \leq l \mid T_i = k) = \Phi(\alpha_{jl} - \beta_j(x_i + s_{ijk}))$ where $\alpha_{j1} = 0$ and $\alpha_{jl} < \alpha_{j,l+1}$ for any j and l . In this model, the latent variable x_i represents the degree to which respondent i is pro or anti-reform while s_{ijk} measures his support level for group $k = 1, 2$ where $s_{ij0} = 0$ and a greater value of s_{ijk} indicating a higher level of support. In addition, the “item difficulty” parameter α_{jl} controls how likely respondents are to agree or disagree with policy j without endorsement, and the “discrimination” parameter β_j operationalizes the degree to which policy j differentiates between pro-reform and anti-reform respondents.¹⁹ We assume $\beta_j > 0$ for any j because we have written policy questions such that a respondent’s agreement would imply he/she is supportive of the reform. Thus, in our model, the probability of agreeing with a reform proposal is a function of the two factors: how pro-reform a respondent is in general and how supportive he/she is of the assigned group. In addition, the degree to which responses are affected by these factors depends on how popular the reform proposal is and how the proposal can discriminate between pro-reform and anti-reform respondents.

We model the two key latent parameters, x_i and s_{ijk} , using the multilevel modeling strategy. Formally, the model is specified as follows,

$$\begin{aligned}
x_i &\overset{\text{indep.}}{\sim} \mathcal{N}(\delta_{\text{village}[i]} + Z_i^\top \delta^Z, 1) \\
s_{ijk} &\overset{\text{indep.}}{\sim} \mathcal{N}(\lambda_{k,\text{village}[i]} + Z_i^\top \lambda_k^Z, \omega_{k,\text{village}}^2) \\
\delta_{\text{village}[i]} &\overset{\text{indep.}}{\sim} \mathcal{N}(\delta_{\text{district}[i]} + V_{\text{village}[i]}^\top \delta^V, \sigma_{\text{district}}^2) \\
\lambda_{k,\text{village}[i]} &\overset{\text{indep.}}{\sim} \mathcal{N}(\lambda_{k,\text{district}[i]} + V_{\text{village}[i]}^\top \lambda_k^V, \omega_{k,\text{district}}^2) \\
\delta_{\text{district}[i]} &\overset{\text{indep.}}{\sim} \mathcal{N}(\delta_{\text{province}[i]} + W_{\text{district}[i]}^\top \lambda_k^W, \sigma_{\text{province}}^2) \\
\lambda_{k,\text{district}[i]} &\overset{\text{indep.}}{\sim} \mathcal{N}(\lambda_{k,\text{province}[i]} + W_{\text{district}[i]}^\top \lambda_k^W, \omega_{k,\text{province}}^2)
\end{aligned}$$

where Z , V , and W are optional covariates at the individual, village, and district levels, respectively. The model is completed by assigning non-informative prior distribution on each parameter.

¹⁹We find that the estimates of β_j are similar across policy questions, indicating that each question made a roughly equal contribution to the final estimates.

Specifically, we assume that each respondent is randomly drawn from a population distribution in his own village, each village is randomly drawn from a distribution of its district, and each district is randomly drawn from a distribution of its province. At each level, covariates can be incorporated and the normal distribution is used. We use Markov chain Monte Carlo to obtain random draws from the joint posterior distribution of relevant parameters. For each model fit, which is accomplished via JAGS (Plummer, 2009), we monitor convergence by running three parallel chains with over-dispersed starting values.

Finally, though the number of non-responses is small, the pattern of missingness is not completely random. Thus, we impute these missing values as part of our model by assuming that the data are missing at random conditional on village and other covariates at individual and more aggregate levels. This mitigates the bias and inefficiency that typically result from list-wise deletion.

Model Specification. We fit two models: a direct exposure model that incorporates a respondent's (or his family's) direct exposure to harm and our key explanatory variables, and an indirect exposure model that draws on the same covariates, but substitutes direct exposure to harm for an individual's awareness of civilians being harmed within his larger *manteqa*. Both models include a common set of theoretically relevant variables (see Appendix A.5). At the individual level, we include a battery of socioeconomic and demographic covariates that have been cited as important determinants of support for terrorist or insurgent groups. These covariates include the respondent's age, marital status (Berrebi, 2007), income level, and years of state and madrassa education (Krueger and Maleckova, 2003; Bueno de Mesquita, 2005; United States Agency for International Development, 2011*b*), ethnicity, and if the respondent is a Pashtun, and whether the tribe he affiliates himself with was deemed already pro-Taliban (Giustozzi, 2008, 52–69).²⁰

The models also include village- and district-level covariates, which include the settlement's altitude to account for difficulty of state control (Fearon and Laitin, 2003), population size, and the number of ISAF- and Taliban-initiated violent events within five kilometers of the village's center one year prior to the survey's launch.²¹ District-level covariates include total expenditures on ISAF Commander's Emergency Response Program (CERP) short-term aid projects in 2010 (ISAF CERP Data, 2005-10); the number of

²⁰For our purposes, the pro-Taliban tribes are the Noorzai, Zadran, Gheljay, and Durrani.

²¹These results were robust to the substitution of violent events within one or ten kilometer radii, of violent events within five kilometers for a longer period of time from 2006 to 2010, and of civilian casualties for the same January-December 2010 period.

villages in a given district that had received NSP-run community development projects by the conclusion of 2010; a dummy variable that indicated whether the district was home to a Taliban-run sharia court system; the area in a given district under opium cultivation (in hectares) in 2010 (United Nations Office of Drug Control, 2010, 112); the length of paved roads, a proxy for general economic development; a dummy variable indicating whether the district neighbored Pakistan, to control for cross-border flows of arms, insurgents, and funds; and ISAF’s own measure of the control it exercised over a given district. We draw on ISAF’s four-fold index of control, which rates districts from “government control or dominant influence” to “local control or dominant influence” to “contested” to “Taliban control or dominant influence.” These ratings were assigned in September 2010, roughly four months before our survey was fielded.²² ISAF- and Taliban-directed aid and service provision variables account for the possibly offsetting positive actions of combatants on the battlefield.²³

4 Empirical Findings

We first examine the relationship between individual-level traits and attitudes before providing evidence of the asymmetric effects of violence on combatant support. We then add nuance to our discussion by examining how intra-Pashtun tribal heterogeneity, along with variation within the Taliban itself, also condition attitudes. Finally, we explore whether post-harm mitigation efforts by ISAF and the Taliban are capable of overcoming intergroup bias in a wartime setting. For ease of presentation, we rely on graphs rather than coefficient tables to demonstrate our main empirical findings.²⁴

4.1 Individual-Level Analysis

Our multilevel models generate estimates of a respondent’s level of support for the particular combatant; estimates are measured in terms of the (posterior) standard deviation of respondents’ preferences within a single dimensional policy space (i.e., ideal points). If a respondent is assigned to the control group, no estimate is generated. Imagine, for example that a respondent is neutral toward the proposed reform initiative. If this individual’s support level for the Taliban was a “1,” then it implies that a Taliban endorsement

²²ISAF “Insurgent Focus” Briefing Slide, dated September 2010.

²³As a robustness check, we re-ran our models without the village and district-level covariates. The results are substantively similar and therefore we present results from the hierarchical models only.

²⁴The posterior mean and standard deviation for each coefficient in our multilevel models are reported in Appendix A.5.

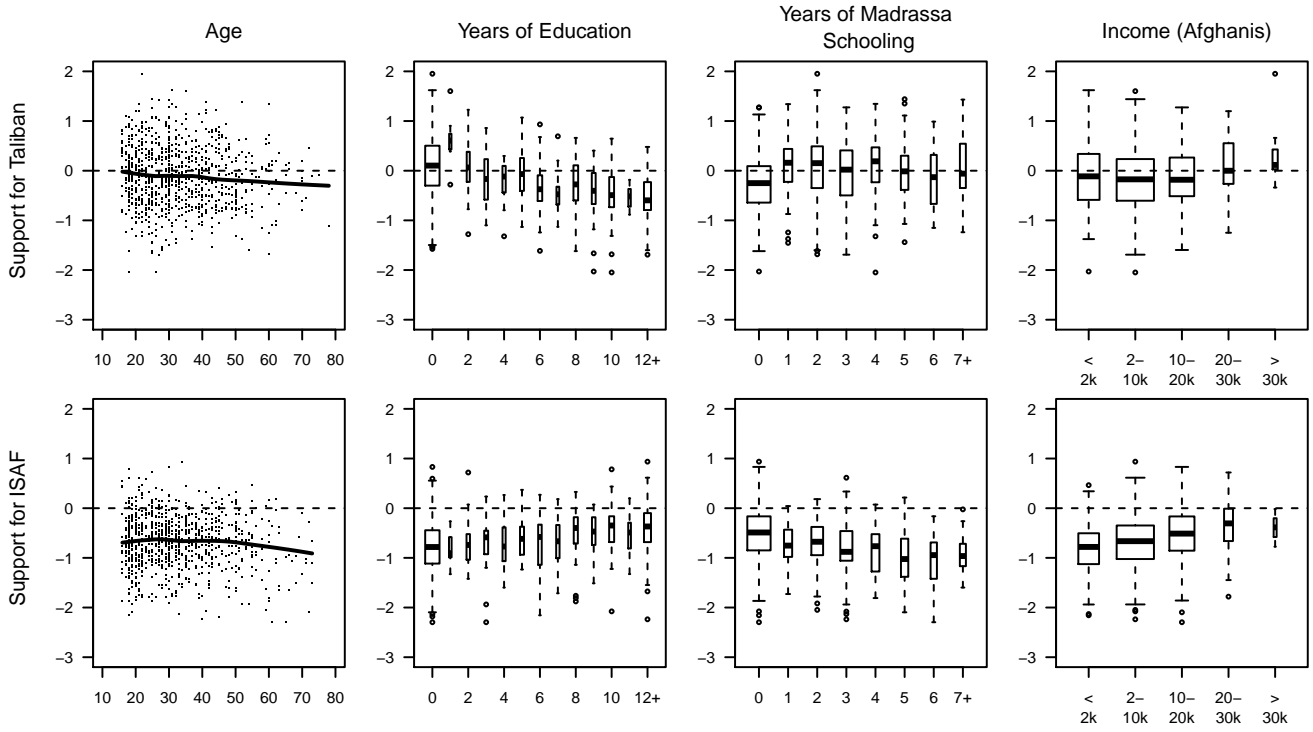

Figure 4: Bivariate Relationships between Demographic Variables and Individual-level Support for the Taliban and ISAF. Support estimates are given in terms of the standard deviation of ideal points. For age (the left column), dots represent respondents and the lowess curve is fitted as a solid line. For remaining plots, box plots are used: the width of each box is proportional to (the square root of) the number of respondents for each value of the demographic variables.

can shift this individual's ideal point by one standard deviation in the pro-reform direction.

Who is more likely to support the Taliban or ISAF? As an initial test of the validity of our survey instrument, we plot individual-level support estimates from the direct exposure model against key demographic covariates in Figure 4. We note that estimated support for both combatants decreases with age, though the Taliban (top row) enjoy more support among the youth than ISAF (bottom row). This may be somewhat surprising given the Taliban's public image as a conservative gerontocracy, but the war has created opportunities for advancement among the youth, and the Taliban appears to be given credit for this mobility. Predictably, support for ISAF — or, more bluntly, decreased dislike for ISAF — is associated with increased education and with fewer years spent in madrassa education. The reverse is true for the Taliban: its estimated support levels rise with years of madrassa education and fall with years of government education. Finally, per capita income is positively associated with estimated ISAF support (or, again, less dislike of ISAF) while there appears to be no clear pattern between income and Taliban support.

Figure 5: Estimated Support Levels for Each Combatant by Victimization Type. We derive and then plot the posterior predicted level of mean support from our multilevel models with 95% confidence intervals.

Attitudes by Levels of Victimization. What are the average support levels for ISAF and the Taliban among those harmed by these combatants? As an initial investigation of the effects of victimization, we estimate the level of support for each combatant according to whether respondents reported harm by ISAF only, the Taliban only, by both combatants, or by neither (Figure 5).²⁵

We find that most respondents are not supporters of either combatant: among those not harmed by either combatant, respondents exhibit strongly negative affect toward ISAF (a -0.62 effect in standard deviations of the ideal points) and are only slightly less negative about the Taliban (at -0.29 standard deviations of the ideal points). Interestingly, those respondents who were harmed by ISAF only or by both ISAF and the Taliban exhibit *positive* affect toward the Taliban (at 0.27 standard deviations and 0.15 standard deviations, respectively). Respondents who had been harmed only by ISAF or the Taliban were the least supportive of these combatants (at -0.89 standard deviations for ISAF and -0.40 standard deviations for the Taliban), though the magnitude of the effect is clearly asymmetrical across combatants.

Asymmetrical Effects of Victimization. We now provide the key evidence to support our central claim that the effects of violence on civilian attitudes are conditional on combatant identity. Figure 6 illustrates the estimated average effects of ISAF (left panel) and Taliban victimization (middle panel) on ISAF and Taliban support at two levels: the individual/family (solid circles) and the *manteqa* (open circles). In the right panel, the net differences between the effects of victimization on support for the Taliban and ISAF are also provided.

²⁵In our empirical analysis, we assume that the effects of harm by each combatant are additive in nature when estimating the level of support for those harmed by both combatants. For the sake of clarity of analysis, we did not include an interaction term in our models. Future research could relax this assumption, however, and generate both theoretical predictions and empirical tests that examine how exposure to harm by multiple combatants affects the direction and magnitude of the asymmetry we observe here.

Figure 6: Estimated Effects of ISAF and Taliban Victimization on Support Levels for Each Combatant. The right panel presents the differences between the results in the middle and left panels. Posterior means of coefficients derived from multilevel models are plotted with 95% confidence intervals.

A number of important observations stand out. First, as expected by Hypothesis 1, we note that ISAF victimization is associated with a significant negative effect on ISAF support. ISAF victimization is also associated with a substantively large positive effect on Taliban support (Hypothesis 2). These data confirm that harmed individuals are both punishing the out-group for inflicting harm and are transferring support to the out-group as expected if intergroup biases are in play.

Second, Taliban victimization has no clear effect on support for ISAF. As expected by Hypothesis 3, we do not observe a blossoming of support for ISAF after Taliban-inflicted harm, suggesting that the out-group is not rewarded for its (relative) restraint. Moreover, Taliban victimization itself only slightly decreases Taliban support and certainly does not approach the “penalty” on ISAF support witnessed after ISAF victimization. While it would be incorrect to conclude that the Taliban can victimize civilians with impunity, they appear to enjoy a much larger cushion of public support than does ISAF, for whom civilian casualties are associated with a steep negative effect on support.

Third, we observe our hypothesized “home team discount” most clearly in the asymmetry of effects between ISAF victimization on Taliban support (middle panel, left column) and Taliban victimization on ISAF support (left panel, right column). This difference is statistically significant and is estimated to be 0.42 standard deviation of the ideal points (with the 95% confidence interval of [0.03, 0.81]) at the individual/family level. The right panel in Figure 6 underscores the asymmetry between the effects of ISAF victimization on relative support for the combatants (Taliban support minus ISAF support) and those associated with Taliban violence. Once again, it is apparent that while ISAF victimization creates a substantial positive effect on net Taliban support, Taliban victimization generates at best only a very modest positive effect on relative support for the out-group.

Are these results driven by personal exposure to harm, as suggested by Hypothesis 5, or are indirect influences equally as important? Returning to Figure 6, we observe that *manteqa*-level effects (as represented by open circles) of ISAF victimization are attenuated when compared with individual self-reports. We find that the net difference in the effect of ISAF violence on ISAF support between the individual- and *manteqa*-level is nearly statistically significant, with a 0.246 (95% confidence interval at $[-0.07, 0.60]$). We do not observe a similar pattern of attenuation for Taliban violence, in part because the individual-level effects are already small. While the general pattern of effects is therefore similar across individual and *manteqa* levels, the magnitude of estimated effects on support levels for each combatant is typically diminished at the *manteqa* level, and significantly so for ISAF.

One interesting wrinkle also emerges from these findings: both Taliban and ISAF endorsements are, in some cases and regions, associated with reductions in support for the proposed reform relative to the control endorsement.²⁶ While caution is warranted, one interpretation of this result is simply that the control most closely resembles an official (government) endorsement. What we may be measuring, then, is the relative shift in support for Taliban and ISAF combatants associated with victimization against a more general backdrop of war-weariness in which neither combatant is especially favored. That said, however, since support in war is relative, not absolute, it is also clear that the Taliban do enjoy a greater measure of support, and more tolerance of inflicting harm on civilians, than ISAF.

Tribal Analysis. Support for combatants is best cast as a continuum (Petersen, 2001, 8), rather than a simple (and misleading) choice of “pro-Taliban” or “anti-ISAF.” We therefore add nuance to our discussion of intergroup bias by exploring intra-group variation. Several Pashtun tribes, for example, have largely (and publicly) declared in favor of the Taliban, while others, often in conflict with pro-Taliban tribes, have remained neutral or in a few instances sided against these tribes. While we cannot assume homogeneity of views among all members of a particular tribe, we can explore whether the attitudes of individuals from these pro-Taliban Pashtun tribes diverge from those of their non-Taliban aligned counterparts.

In particular, we expect that individuals from pro-Taliban tribes are more likely to be forgiving of

²⁶Our breakdown of responses by question and province are provided in the Appendix. Since the control provides the baseline for assessing ISAF and Taliban endorsements, support for the control is measured as the reverse of the Taliban or ISAF endorsement.

Figure 7: Differences in Estimated Effects of Victimization by the Taliban and ISAF on Their Support Levels by Tribal Affiliation with the Taliban. The right panel presents the differences between the results in the middle and left panels. Posterior means of the corresponding coefficients are plotted along with 95% confidence intervals. The full results of these models appear in Appendix A.5.

Taliban victimization given their prior identification with the Taliban. The negative effects of ISAF victimization are also likely to be greater in magnitude for this subset, though if ISAF support is already low we may observe a floor effect given that support for ISAF may not sink any further. In each case, victimization is likely to confirm the intergroup bias that negative in-group actions are situational in nature while those of the out-group and its members are dispositional.

Figure 7 illustrates the conditional effects of tribal affiliation on how ISAF and Taliban victimization is interpreted by our respondents. We begin with the effects of ISAF victimization on support for ISAF and the Taliban among pro-Taliban tribe (solid circles) and non-pro-Taliban tribe (solid squares) members, then turn to how Taliban violence affects support for ISAF and the Taliban itself.

We find, for example, that ISAF victimization has a more pronounced negative effect on ISAF support among pro-Taliban tribe members than their non-pro-Taliban tribal counterparts. Notably, however, the difference itself is fairly modest at -0.32 standard deviations (95% confidence interval at $[-0.90, 0.19]$) and statistically insignificant. The effects of ISAF violence on support for the Taliban are also different across sub-groups. Here, it is the non-pro-Pashtun tribes that record the largest positive effect on support for the Taliban after experiencing ISAF victimization. This result is likely due to two factors. First, it is probable that since pro-Taliban tribes have already decided for the Taliban, their support is subject to a ceiling effect that limits the magnitude of the positive shock to Taliban support. Second, this result suggests that ISAF violence has an outsized effect on individuals who believe that they are either neutral or (more rarely) who have sided with ISAF. The difference between these two groups is striking at -0.59 standard deviations (with a 95% confidence interval of $[-1.06, -0.22]$), suggesting that ISAF-inflicted

harm has a large effect on members of non-Taliban-aligned tribes and their support for the Taliban.

The effects of Taliban victimization on support for the combatants is also conditional on tribal affiliation, though less so than in ISAF's case. Taliban victimization has broadly similar effects on ISAF support for both pro-Taliban and non-aligned Pashtuns, for example. This result is consistent with our expectation that intergroup bias prevents a transfer of support from the in-group to the out-group. Where we observe divergence between these two subgroups is in the effects of Taliban violence on Taliban support. Members of pro-Taliban tribes appear not only to tolerate but embrace harm, as witnessed by the *positive* effect of Taliban harm on Taliban support. By contrast, Taliban violence has a slightly negative effect on non-pro-Taliban tribal members' support for the insurgent organization. Unsurprisingly, the difference between the two groups is statistically significant at 0.57 standard deviations (with a 95% confidence interval of [0.05, 1.14]).

These findings deepen our previous discussion by suggesting that combatant violence has asymmetric effects across different Pashtun tribal affiliations. Viewed from ISAF's perspective, it is important to recognize that ISAF victimization has a disproportionate effect on support for the Taliban among non-pro-Taliban tribal members. The Taliban, by contrast, appear to enjoy more than simply a cushion of support among pro-Taliban tribal members. Instead, the Taliban's violence has a positive (and large) effect on pro-Taliban tribal members, suggesting that the Taliban possess a far higher freedom of action—to include causing civilian casualties— among their supporters than ISAF.

Effects of Post-Harm Mitigation Efforts. Can combatants offset the negative effects of their violence by rendering post-harm assistance? We offer a preliminary exploration of this issue in Figure 8, which presents the estimated combined effect of being harmed but not subsequently approached (circle), the effect of being approached (square), and the combined effect of victimization and receiving post-harm assistance on attitudes toward the combatants.

Two broad conclusions stand out. First, post-harm mitigation efforts by both combatants are associated with a marked negative effect on support for the *other* combatant. Taliban victimization alone has a small positive effect on attitudes toward ISAF (as reported above) but, once aid has been proffered, the effect is a substantially negative effect on attitudes towards ISAF. Similarly, experience with ISAF victimization

Figure 8: Estimated Effects of Victimization and Subsequent “Approach” by Combatants on Support. The right panel presents the differences between the results in the middle and left panels. Posterior means of the corresponding coefficients are plotted along with 95% confidence intervals.

alone is associated with a positive effect on support for the Taliban. Yet if aid has been provided by ISAF, the result is a large negative effect on Taliban support (second column). Indeed, the net difference in effect between individuals who were harmed but not approached by ISAF and those who were harmed and then approached is a highly significant -1.00 standard deviation movement *away* from a pro-Taliban position (95% confidence interval of $[-1.44, -0.53]$)

An optimistic take on these results would suggest that hearts and minds can in fact be swayed, if not bought outright, via post-harm mitigation efforts. Yet a second finding is also important: these efforts appear to have little effect on support for the actual combatant that rendered the assistance. While ISAF does appear more successful at generating modest positive effects after its efforts, there is much less positive movement in attitudes toward the combatant responsible for the victimization than there is a shift away from the other combatant. In this situation, post-harm aid appears less about persuading civilians to move *toward* one’s side as it is about shifting *away* from the rival combatant.

We must also be careful not to overstate the finding about the effects of ISAF assistance. There is a severe selection problem at work here, because ISAF managed to “approach” only 16% of those who claimed that they had been harmed by ISAF. By contrast, the Taliban “approached” over 60% of those who self-identified as suffering Taliban victimization. ISAF’s decision-making on the extension of condolence and battle damage payments is often haphazard, but is at least partly conditioned on anticipated reception in a given village (Campaign for Innocent Victims in Conflict, 2010b). The more likely a unit is to receive armed resistance from aggrieved villagers, the less likely ISAF will return to disburse payments. Given closer media scrutiny, mass casualty events are more likely to be followed by post-harm mitigation efforts.

Aggrieved individuals in small-claims cases, by contrast, are often forced to go to military bases to receive their funds, discouraging all but the most determined and risk acceptant claimants (Campaign for Innocent Victims in Conflict, 2010a). As a result, the finding regarding ISAF's ability to use condolence payments to overcome intergroup bias relies on a small subset of individuals who were specifically selected to receive this assistance. Indeed, these individuals may be the ones most likely to be swayed by ISAF's efforts.²⁷

Taking these findings as a whole, we uncover substantial evidence to support claims that the effects of violence on attitudes are conditional on perpetrator's identity. ISAF's violence is strongly associated with a negative effect on attitudes toward ISAF, while Taliban violence only has a marginally negative effect on Taliban support. Similarly, ISAF victimization leads to a marked positive effect on Taliban support but, consistent with our expectations, Taliban victimization results in only a small positive effect on ISAF support. These asymmetries are often powerful among a subset of individuals, namely, those who claim membership in publicly pro-Taliban Pashtun tribes. Finally, these results appear to be largely driven by personal experiences with harm, rather than indirect knowledge of harm inflicted within an individual's *manteqa*, especially for ISAF violence. This finding reinforces the need to devise and test our arguments about civilian victimization at the most micro-level unit possible — that of the individual — rather than assuming that macro-level effects scale down to the individuals in a given geographic space.

4.2 Village-Level Analysis

These findings also pose a substantial challenge to studies that presume individual- or group-level motives and mechanisms but test these arguments with data aggregated to larger territorial units such as villages or districts. As noted above, our violent event datasets are only weakly correlated with respondent perceptions of harm. This lack of a relationship carries over into our multilevel model, in which ISAF and Taliban violent events from January to December 2010 are not associated with respondent attitudes toward the combatants regardless of whether we rely on a 1km², 5km², or 10km² radius around the village. Simply put, once we control for variance at the individual level and varying intercepts at the village, district,

²⁷Intriguingly, a study of 155 recipients of USAID's Afghan Civilian Assistance Program I (ACAP I)—which provides cash grants and small bundles of household items to victims of ISAF and Taliban violence—found that satisfaction with this aid hinged on who had inflicted the violence. Only 45% of recipients were satisfied with ACAP assistance after experiencing ISAF victimization, compared with nearly 85% of recipients after experiencing insurgent violence. See United States Agency for International Development 2011a, 10.

and province level, other factors at the village and district levels are not strongly associated with combatant support.²⁸

To be sure, not every research question requires individual-level data, and we must be cautious when assessing causality in the absence of a clear identification strategy. Yet these non-findings suggest that the now-standard practice in civil war studies of relying on aggregated event counts may be problematic. At a minimum, these data are unlikely to be useful in testing the attitudinal mechanisms thought to link violence to behavior. Even studies that draw on fine-grained data on civilian casualties (Condra et al., 2011) are likely to be misleading if these events are only loosely connected with civilian perceptions or are aggregated into larger territorial units far removed from the victimized individuals. In other words, civilian attitudes may represent a substantial omitted variable in most statistical accounts of civil war dynamics. These mistaken inferences are likely compounded if the event data are not disaggregated by perpetrator and victim identities, thus missing the conditional nature of violence's effects on civilian attitudes.

4.3 Alternative Explanations

Our findings strongly suggest that intergroup biases are responsible for the observed asymmetries of effects of combatant actions on civilian attitudes. Yet what of alternative explanations? We consider four alternative identity-based theories and three additional explanations that emphasize battlefield factors such as the distribution of aid, relative control by the combatants, and Taliban service provision.

Other Identity-Based Accounts. We might imagine, for example, that the observed asymmetry of effects arises from a sense of betrayal among civilians. Perhaps these individuals expect that ISAF, but not the insurgents, will protect them, a belief that leads them to punish ISAF for violating its perceived commitment to safeguard the population. While intuitive, it is apparent that few believe ISAF will protect them from harm; in fact, the opposite is true. We posed the question “In your view, how often do foreign forces [Taliban] take precautions to avoid killing or injuring innocent civilians during their operations?” Possible answers were: always (3), sometimes (2), rarely (1), and never (0). The mean response for ISAF was 0.56; for the Taliban, a 1.92, a substantial difference.²⁹ These findings are stunning when we consider that the

²⁸Note, too, that this criticism extends to other key village-level data such as elevation and population size, which are not significantly associated with support for combatants in any of our models.

²⁹This difference is significant at $p = .000$, $t_{5506} = 56.55$.

Taliban killed an estimated 2,080 Afghan civilians in 2010 alone while ISAF was deemed responsible for 440. Yet the perception remains that ISAF, rather than the Taliban, is wielding violence indiscriminately, suggesting that individuals in our sample area do not believe that ISAF is protecting them.³⁰

These findings are also consistent with arguments that the post-2001 status reversal experienced by Pashtuns in Afghanistan's ethnic hierarchy has created high levels of support for the Taliban (for status reversal arguments, see especially Petersen 2002, 40-61). Yet while it is true that foreign-imposed regime changes often upend existing institutions, this is less the case in Afghanistan than elsewhere. The Karzai-led government created by the Bonn Agreement (December 2001) actually represented a return to prior patterns of ethnic hierarchy, not a decisive break. The current Pashtun-dominated executive has echoes in earlier Durrani Pashtun regimes, including the rule of the "Iron Amir" (1880-1901), under Mohammed Nadir Shah (1930-79), and the Taliban era itself. Despite (modest) local score-settling, Pashtuns were not collectively punished for their earlier support of the Taliban, and the new Afghan constitution itself was ratified unanimously (Barfield, 2010, 272-93). Given that dissatisfaction with the Karzai government transcends ethnic lines, it is unlikely that current Taliban support among Pashtuns — itself variable, not constant, in our data — is due to status reversal.

A third alternative explanation privileges revenge motives arising from the Pashtun-specific code of ethics known as *Pashtunwali*. Consisting of nine principles, *Pashtunwali* norms call for aggrieved individuals to take revenge (*badal*) upon a wrongdoer while acting bravely (*tureh*) to defend their property, family (especially women), and honor (Johnson and Mason, 2008; Tomsen, 2011, 47-54). This argument about culture dictating attitudes stumbles, however, over two issues. First, it is not clear why attitudes would be asymmetrical among harmed individuals without invoking a prior claim about intergroup bias. In principle, revenge-seeking should lead to symmetrical effects of violence on civilian attitudes since the obligation to seek redress is not directed solely against non-Pashtuns. Second, there is considerable intra-Pashtun tribal differences in how their attitudes are influenced by combatant violence and subsequent restitution efforts. It is neither the case that Pashtun attitudes are monolithic toward the combatants, nor

³⁰According to UNAMA's figures, the Taliban has been responsible for the bulk of civilian deaths since at least 2008. In 2008, ISAF was responsible for 828 deaths to 1,160 by the Taliban; in 2009, ISAF inflicted 596 deaths, compared with 1,631 by the Taliban (see United Nations Assistance Mission in Afghanistan, 2011). This raises a key methodological problem for observational studies if the objective coding of responsibility and the perceived blame by the victimized individuals are not highly correlated.

are these attitudes uniformly affected by combatant actions.

Finally, these asymmetrical effects remain regardless of an individual's level of prior exposure to ISAF. Contact theory (Allport, 1954; Cook, 1971) suggests that, under certain conditions, intergroup bias — and, specifically, the lessening of out-group derogation — can be reduced via frequent, positive interaction with members of the out-group. Current ISAF counterinsurgency doctrine also stresses the importance of face-to-face interaction with local populations to build trust and shape attitudes. There is little evidence to support this claim in our context, however. To begin with, the conditions cited as necessary for contact theory to be operative are daunting. These include equal status between the interacting parties, shared goals, sustained intimate contact, and the absence of competition (Paluck and Green, 2009, 346), a set of conditions absent in Afghanistan. We also directly tested this claim with a question that measured the respondent's frequency of prior interaction with ISAF forces (*Frequency*). *Frequency* was statistically significant and negatively associated with ISAF support, exactly the opposite of contact theory's predictions.

Battlefield Dynamics: Aid, Control, and Taliban Service Provision. How do other theoretical explanations fare in explaining civilian attitudes? Surprisingly, we find little evidence that district-level variables hold weight in explaining attitudes toward either combatant. Caution is warranted when interpreting these results, to be sure, because there are only 21 districts in our sample. Moreover, while our sample is randomly drawn, combatant decisions to allocate aid and services, and to wield violence are not, suggesting that some endogeneity between district-level variables and attitudes may be present. We therefore draw solely on bivariate correlations in the analyses detailed in Figure 9.

Economic assistance, whether in the form of quick, 30-day Commanders' Emergency Response Program (CERP) initiatives or more deliberate National Solidarity Program (NSP) community grants, appears to hold little sway over attitudes. This holds true if we replace our preferred CERP measure, dollars spent per district in 2010, with the number of CERP initiatives undertaken per district in 2010. Similarly, our measure of NSP progress, namely the number of villages in a given that received NSP grants up until December 2010, is not associated with any effect on civilian attitudes. While data limitations, especially given poor CERP data management practices, are undoubtedly present, a district-level analysis may nonetheless be justified given the possibility of spillover between villages in a given area for certain types of aid.

Figure 9: Relationship between District-Level Covariates and Estimated District-Level Support for the Taliban and ISAF. The estimated mean support levels and 95% confidence intervals for each combatant (solid circles and squares) are presented along with net differences (open triangles).

The apparent ineffectiveness of the US \$1 billion National Solidarity Program deserves a closer look, not least because it partly conflicts with Beath, Christia and Enikolopov (2011)'s careful NSP evaluation. These authors conclude that NSP receipt is associated with a modest improvement in respondents' attitudes toward both local and central governments in eight of 10 targeted districts. This positive effect disappears, however, in the two most violent and Pashtun-dominated districts in their sample, a finding that jibes with our own findings (Beath, Christia and Enikolopov, 2011, 4). Broadly speaking, the different conclusions about NSP effectiveness stem from sampling decisions: our 21 districts are all majority Pashtun and much more violent than average (Tajik majority) districts, while Beath, Christia, and Enikolopov restrict their sample to mostly Tajik or Hazara dominated areas (six of 10 districts in their sample) where only 3% of respondents indicate that their village had experienced an attack in the past year (Beath, Christia

and Enikolopov, 2011, 16).³¹ Moreover, these differences may also arise from different methodological choices: we chose to rely on endorsement experiments to minimize social desirability bias, while the NSP survey evaluation relied on direct questions.

We also find only modest evidence for the presumed relationship between the distribution of combatant control and civilian attitudes. While being located in a government-controlled district is predictably associated with a negative effect on Taliban support, no level of combatant control is associated with any statistically significant effect on support for either combatant. ISAF support is lowest, and Taliban support highest, in districts that are deemed “Taliban controlled” by ISAF relative to “contested” districts. This is consistent with the theoretical predictions of Kalyvas (2006), though the level of support for the Taliban is surprisingly low and, indeed, does not reach positive values for most of the districts in the analysis (Row 1). And as Figure 3 reveals, we also observe considerable within-district heterogeneity in attitudes, especially those toward the Taliban, despite the level of control being held constant. In an ideal environment, control data would exist at the village level, as gathered by Kalyvas for the Greek Argolid (1943-44), to permit a more direct test. Indeed, our analysis reveals that ISAF’s district-level conception of control may be too crude to capture the substantial village-level variation that exists in Afghanistan.

Taliban support is also consistently *lower* in districts marked by high opium cultivation. While the Taliban do provide farmers with security in exchange for a share of revenue from opium sales, it is possible that more draconian Taliban measures — cultivation quotas enforced through violence, increasing levels of taxation, and leverage due to rising farmer indebtedness — account for these lower levels of Taliban support. Unexpectedly, the districts that were earliest to witness mobile Taliban courts established have lower net support for the Taliban, though this difference is not statistically significant. This difference is perhaps due to the fact that the Taliban chose these locations to win over local populations, not to reward areas where support was already assured.

Finally, we examined whether districts that border Pakistan differ in their levels of support for the Taliban than non-border districts. One might imagine, for example, that these border districts have a higher concentration of foreign fighters than more distant districts such as Helmand or Uruzgan, and thus

³¹Note, too, that Beath, Christia, and Enikolopov included female respondents in 406 of their 500 villages, something that was not feasible in our sampling environment.

the meaning of “Taliban” may differ regionally.³² We therefore plot the mean differences in support for Taliban and ISAF, along with the net difference, in the final column of Figure 9. There is little difference in support for either combatant between border and non-border districts.

5 Potential Threats to Inference

It is worthwhile to note that information may be unreliable, and uncertainty rife, in wartime settings. Individuals themselves may not know which combatant to blame for the harm inflicted, especially if they are literally caught in the crossfire. Individuals may also be biased against the outsider, leading to the over-reporting of harm by the out-group. Under this scenario, blame attribution may be at work.³³ Nevertheless, in contrast to our intergroup bias argument, this alternative theory does not predict the asymmetry in the marginal effects of victimization. Instead, a theory of blame attribution would suggest that the effects of victimization are uniform across combatants even though self-reports may incorrectly attribute some of the harm inflicted to the out-group.

Two potential objections to our intergroup bias theory should also be addressed here. First, it is possible that perceptions of harm inflicted are themselves driven by prior attitudes toward the combatants. Willingness to assign blame for harm may therefore be endogenous to preexisting beliefs, particularly in circumstances where the actual identity of the perpetrator is unknown. Addressing this issue is difficult due to the absence of completely reliable measures of violence inflicted on individuals. In addition, research in conflict settings is typically conducted after repeated interactions between combatants and civilians have already occurred. Nevertheless, our theory generates a clear set of predictions about *asymmetrical* effects, whereas claims about endogeneity between attitudes and perceptions of harm do not. Specifically, the presence of endogeneity implies that self-reported harm by any group is negatively correlated with support for that group and does not predict that these effects are conditional on the perpetrator’s identity.

A second concern is that since groups vary along multiple dimensions, not simply ethnicity, these differences in political objectives and military strategies may matter more than intergroup bias. In general, addressing such a concern would require the researcher to manipulate certain aspects of the identity and/or

³²We thank a reviewer for this suggestion.

³³We thank the associate editor and a reviewer for raising this possibility.

actions of combatants while keeping the ethnicity difference constant. Clearly, this is a difficult task in a wartime context. In our case, we can rule out specific explanations. For example, one may hypothesize that since ISAF is an external intervener, it possesses a shorter time horizon than the Taliban, the local in-group, and thus individuals will respond differently to their actions. However, this hypothesis is unlikely to hold in our case. While external interveners can of course withdraw, this prospect does not necessarily predict asymmetrical effects of harm. Moreover, an individual's "shadow of the future" would also have to loom exceedingly large for these distant concerns to trump short-term survival calculations.³⁴

6 Concluding Remarks

The premise that civilians in wartime, trapped between dueling combatants, are driven solely by material inducements and immediate or threatened punishment remains a central facet of our theories of civil war dynamics. Our evidence suggests a more complicated picture: civilians possess strong intergroup biases that condition how violence will affect support for combatants. Moreover, these effects are asymmetrical, not uniform, in nature. In Afghanistan, ISAF's violence is associated with a negative effect on attitudes toward ISAF, while Taliban violence does not produce a similarly negative effect. Moreover, ISAF's victimization is associated with a positive effect on Taliban support; Taliban victimization, by contrast, does not lead to a transfer of support to ISAF. This asymmetrical "home team discount" is especially strong among self-declared pro-Taliban tribes. Nor are these effects fleeting. These asymmetrical effects persist even when controlling for key factors such as each combatant's level of control over a district, their prior patterns of violence, and their efforts to provide economic assistance and basic services.

These findings suggest several implications for the current war in Afghanistan and, more generally, for the study and practice of counterinsurgency. First, rebels who are in-group members possess a measure of forgiveness not afforded the counterinsurgent when it victimizes civilians. In fact, ISAF violence has most likely reinforced intergroup biases, making it even more difficult to sway, let alone win, "hearts and minds." Nor does it appear that aid programs, whether the massive National Solidarity Program or small-scale Commander's Emergency Response Program funds, are making substantial in-roads on this task. To

³⁴Our survey also preceded President Barack Obama's June 2011 announcement of the American withdrawal from Afghanistan.

be sure, more research is required, given that our sample included only 21 districts. Yet these programs do appear insufficient to provide the kinds of material inducements that might overcome intergroup biases. The durable nature of these biases also suggests they will persist through 2014, complicating ISAF's planned exit from Afghanistan.

Our survey also provides a proof of concept for the utility of experimental methods in violent settings. Scholars, non-governmental organizations, and military forces alike could benefit from replacing direct questions with indirect survey techniques such as endorsement and list experiments. In Afghanistan, for example, ISAF has devoted tens of millions of dollars to assessing public opinion on a wide array of sensitive issues using direct questions, including on corruption and support for the Afghan government, Taliban, and Afghan National Security Forces. Given the methodological and ethical issues associated with direct questions in wartime environments, such efforts are unlikely to yield credible data on public opinion that policymakers require. At the other extreme, the World Bank's signature Living Standards Measurement Survey avoids sensitive topics and typically does not record data on exposure to violence, even when fielded in (post-)conflict environments (Brück et al., 2010). Between these two extremes, there is enormous opportunity to use and combine multiple indirect techniques to tackle sensitive issues of pressing theoretical and practical importance.

That combatant violence has asymmetrical effects on civilian attitudes also raises implications for existing theories of civil war violence. Most importantly, this asymmetry underscores the need to consider the psychological mechanisms that may drive civilian behavior in wartime. In part, this may result in the broadening of our understanding of individual incentives to include non-material and group-based incentives as well as material inducements and punishments. Equally important, however, is the role played by perceptions of harm, as measured by self-reports. No single event dataset, or even multiple ones, will capture the complete array of violence experienced by a population during wartime, especially if these data remain narrowly focused (as now) on civilian fatalities only. Rather than relying solely on event data, we should integrate perceptions of harm and other individual-level characteristics into our models if we are to understand how violence is understood by civilians and how it affects both attitudes and subsequent behavior. Given that ISAF's own event data had little explanatory weight in our models,

village level or even coarser data are likely inappropriate for testing theories that assume individual- or group-level motives and mechanisms.

As a part of this process, empirical strategies will need to move beyond the simplistic assumption that violence has uniform effects. Statistical models that rely on counts of violent acts but do not distinguish among perpetrator and victim identities are likely to be misspecified, for example. Instead, we should be devising and testing theories that measure conditional average treatment effects if we are to properly capture the heterogeneous effects of violence on attitudes. This move is especially important for explaining why certain policies worked (or failed) and identifying why certain individuals (but not others) were more responsive to particular initiatives. Beyond violence, measurement of the effectiveness of aid interventions would also likely benefit from considering whether program effects are conditional on donor identity.

Finally, we still know little about how group identities form under wartime conditions or how blame for particular events is assigned by affected individuals. Reversing this study's focus to treat identity as the dependent variable would provide insight into the dynamics of blame in wartime settings. Perhaps most ambitiously, future research should strive to close the loop between attitudes and behavior. Estimates of support could become the basis for predicting the location of future violence or the degree of collaboration with the local population, highlighting again the importance of elevating civilian attitudes from their current neglected status in our theories to the foreground of our study of civil war dynamics.

A Appendix

A.1 Endorsement Experiment Questions

In addition to the prison reform question given in Section 2.1, we used three other questions in order to estimate support levels for the Taliban and ISAF.

Direct Elections

First, we asked whether individuals would support a proposal to allow Afghans to vote in direct elections when selecting leaders for district councils. While technically permitted under Afghanistan's 2004 Electoral Law, these elections have not been held to date. In early 2010, the Independent Directorate for Local Governance (IDLG) — a government agency led by a presidential appointee that works with ISAF to coordinate subnational governance policies — publicly floated the idea of direct elections, to be held in March 2011 (they were not). Surprisingly, the Taliban seized upon this idea in their own propaganda, suggesting that Karzai's claims of being democratically elected were hollow since the Electoral Law was not being followed (Nixon, 2011). Given the issue's long-standing nature, individuals were familiar with it and the various proposals for (finally) allowing elected district councils. The question reads as follows,

It has recently been proposed [by the Taliban; by foreign forces] to allow Afghans to vote in direct elections when selecting leaders for district councils. Provided for under Electoral Law, these direct elections would increase the transparency of local government as well as its responsiveness to the needs and priorities of the Afghan people. It would also permit local people to actively participate in local administration through voting and by advancing their own candidacy for office in these district councils. How do you feel about this proposal?

Independent Election Commission

Second, we gauged support for reform of Afghanistan's Independent Election Committee (IEC), a much-maligned institution that failed to prevent widespread fraud in the 2009 Presidential and 2010 Parliamentary elections. The Afghan public has also soured on the IEC; only 54% approved of its performance in 2010 (The Asia Foundation, 2010). ISAF and various international organizations spent much of the post-September 2010 election period publicly discussing various reform proposals. Even the Taliban, which had sought to derail these elections through violence, raised the IEC as additional evidence of the Karzai administration's democracy deficit (Nixon, 2011). Given that the IEC subsequently voided over 20% of the ballots cast (about 1.3 million), respondents were well aware of the IEC and its flaws when prompted for their opinion. Below, we reproduce this question,

A recent proposal calls [by the Taliban; by foreign forces] for the strengthening of the Independent Election Commission (IEC). The Commission has a number of important functions, including monitoring presidential and parliamentary elections for fraud and verifying the identity of candidates for political office. Strengthening the IEC will increase the expense of elections and may delay the announcement of official winners but may also prevent corruption and election day problems. How do you feel about this proposal?

Anti-Corruption Reform

The final question asked whether individuals would support strengthening the new Office of Oversight for Anti-Corruption. Alongside security concerns, there is perhaps no more salient issue in the minds of Afghans today than corruption; a full 76% rated it a “major problem” in 2010, ranking it among the top two domestic concerns of individuals (The Asia Foundation, 2010). Both ISAF and the Taliban are aware of the issue’s salience; each has issued repeated public statements concerning corruption in general and the need to strengthen existing institutions, including the Office of Oversight, in particular (Office of the Special Inspector General for Afghanistan Reconstruction, 2009; Konrad-Adenauer-Stiftung, Royal United Services Institute and Transparency International UK, 2011). The question is given below,

It has recently been proposed [by the Taliban; by foreign forces] that the new Office of Oversight for Anti-Corruption, which leads investigations into corruption among government and military officials, be strengthened. Specifically, the Office’s staff should be increased and its ability to investigate suspected corruption at the highest levels, including among senior officials, should be improved by allowing the Office to collect its own information about suspected wrong-doing. How do you feel about this policy?

A.2 “Ground-Truthing” Our Initial Findings

Since endorsement experiments only provide indirect measures of support, it is important to compare these responses with existing knowledge of these areas. We contend that, while these distributions are broadly consistent with the qualitative knowledge about these five provinces, our survey experiment also identifies novel patterns at provincial and district levels.

As Figure 1 demonstrates, Helmand reveals a strong pro-Taliban emphasis in its collective response to the endorsement questions at the provincial level. This finding is perhaps unsurprising, for Helmand has been a Taliban bastion since the resurgence of the Taliban movement in 2006. Afghanistan’s largest province, a key South-North supply line, and the center of its booming opium trade, Helmand has also consistently topped ISAF charts for insurgent-initiated attacks against ISAF forces. In 2010 — that is, before and during our survey — ISAF and Afghan National Army (ANA) forces had launched a series of operations designed to evict the Taliban forcibly from several districts, including Garmser, Nawa, Nad Ali, Now Zad, and the capital, Lashkar Gah. These efforts have yielded a modest reduction of anti-ISAF violence, but these gains remain fragile and their ultimate effects unknown.

Khost is a relatively small and mountainous province that, owing to its strategic location bordering Pakistan, has emerged as an important transit route for both Taliban fighters and those of the Haqqani network. Closely aligned with the Taliban, the Haqqani network is led by Mawlawi Jalaluddin Haqqani and his son, Sirajuddin Haqqani, and has gained a reputation as one of the most lethal and violent insurgent organizations in Afghanistan. At the time of our survey, Khost was largely stable, but had recorded a notable uptick in attacks in 2010 when compared with the preceding year. The presence of both a sizable ISAF contingent and these armed groups lends Khost the air of a classic “battleground” province. As a consequence, attitudes toward the combatants appear nearly evenly divided, with ISAF or Taliban leanings apparently dictated by the content of the particular issue rather than prior allegiance.

Much like Khost, Kunar is a relatively small, mountainous province that borders Pakistan. Two insurgent groups, the Taliban and Hezb-e Islami Gulbuddin (HIG), are present, though the Taliban are by far the largest and most important organization. Unlike Khost, however, Kunar has long been viewed by ISAF as a linchpin in its eastern strategy. As such, at least \$70 million in aid has been poured into the province, while the United States maintains a large, if still insufficient, military presence in the province. Here, too, public attitudes toward the combatants appears divided, with the weight of a particular endorsement conditional on the question posed. This is perhaps to be expected given the sizable presence of both combatants in the province, not to mention ever-increasing levels of violence between them. Kunar will only gain in importance in the coming months as ISAF shifts its counterinsurgency strategy away from Helmand and Kandahar and toward Afghanistan's eastern border provinces.

Logar has until recently enjoyed a reputation for safety, with some of the lowest recorded totals of insurgent violence among Pashtun-majority provinces. While an important transit route to and from Kabul, there is only a minimal Czech-led ISAF force presence in the province. In recent years, however, the Taliban have made inroads into this agricultural province as part of their strategy to encircle Kabul, and violent incidents increased in 2010. Our endorsement experiments reflect this trend: three of four questions suggest a pro-Taliban leaning, despite the fact that Logar's capital, Pul-i-Alam, is only 60 kilometers from Kabul.

Uruzgan is a rugged, sparsely populated and extremely poor (even by Afghanistan's standards) province that has only a small Dutch-led ISAF presence. Local government has essentially been captured by Matiullah Khan, a local warlord who heads a private army that generates millions of dollars by guarding NATO's supply convoys that transit the highway linking Kandahar to Uruzgan's capital, Tirin Kowt.³⁵ Khan, along with US and Australian Special Forces, has also fought to clear Taliban forces from Uruzgan, though allegations persist that he actually colludes with, rather than combats, Taliban forces to secure additional revenues for "protection." In light of the province's chaotic government, weak ISAF presence, and general lawlessness, the demonstrated support for the Taliban in Figure 1 is perhaps unsurprising despite ISAF's own internal designation of Uruzgan as generally under "government or local control."

Finally, Figure 10 offers Helmand as an example that substantial district-level variation exists in the distribution of responses, even within a province uniformly regarded by ISAF and outside observers as heavily pro-Taliban. Intriguingly, in the case of Lashkar Gah, Helmand's capital district, we even observe high levels of ISAF support. This trend is likely due to a joint ISAF-Afghan National Army (ANA) offensive launched in late-2010 that resulted in the forced dislodging of Taliban fighters from the capital city, if not the surrounding countryside. Unlike other provinces, however, Helmand has a fairly high refusal to answer rate, which is mostly concentrated in Now Zad district. Subsequent interviews with our Helmand survey coordinator and district managers suggests that the survey was conducted during an ongoing ISAF military operation that had bloodied, but not yet eliminated, the Taliban in Now Zad.³⁶ Historically a Taliban bastion, Now Zad was a "no man's land" in January-February 2011 and, as such,

³⁵See "With U.S. Aid, Warlord Builds Afghan Empire," *New York Times*, 5 June 2010.

³⁶Interview with project supervisor, Kabul, 4 September 2011; Interview with Helmand project manager, Konduz City, 6 September 2011.

Figure 10: Within-District Distribution of Responses to the Endorsement Experiment for Helmand Province. Plots show the distribution of five point scale responses to four policy questions (columns) across three groups (Taliban/ISAF endorsement groups and control group) for each of the five districts of the Helmand Province in the sample. Sample sizes are also shown.

many respondents simply refused to answer these questions to avoid incurring Taliban wrath. Given these circumstances, it is nonetheless remarkable that the majority of respondents in Now Zad still answered these questions.

Figure 11: Covariate Balance Across Surveyed Villages and Non-Surveyed Villages in Sampled Districts.

A.3 Sampling Balance Tests

The multi-stage random sampling of provinces within the universe of 13 Pashtun-dominated provinces, then districts, then villages guarantees balance across covariates in expectation. Figure 11 shows that the balance is also achieved between surveyed villages (black density lines) and non-sampled villages in sampled districts (dark gray density lines).

A.4 Exposure to Violence

The questions about exposure to violence are reproduced below.

- Over the past year, have you or anyone in your family suffered harm due to the actions of foreign forces [Taliban]?
- Over the past year, have you heard of anyone in your *manteqa* suffering harm due to the actions of foreign forces [Taliban]?

The same questions were asked about the Taliban to establish the comparison between the effects of ISAF and Taliban-inflicted harm on attitudes. *Manteqa* literally translates as “area” and typically refers to a geographic space larger than the village but much smaller than a district. To avoid ambiguity and differing interpretations, the questions were preceded by a script that defined “harm” as both physical injury and property damage.

After each question about direct and indirect exposure to harm, we asked whether the individual had personally experienced or heard about efforts by the responsible combatant to mitigate the harm inflicted. These questions permit sub-setting of individual experiences by exposure to harm (yes/no), by combatant, and whether those harmed were subsequently approached by the responsible party in an effort to mitigate the negative effects of their actions. This latter comparison is especially important since it allows us to examine whether attitudes are irretrievably hardened by violence or whether they can be shaped, if only partially, by combatants after the fact. Our post-harm mitigation question is reproduced below.

- (If yes to the above question) Have you (or your family) been approached by foreign forces after they caused harm?
- (If yes to the above question) Have you heard whether foreign forces approached those who suffered harm?

As before, these questions were repeated to capture whether the Taliban had approached victimized individuals (direct exposure) and if the respondent knew of similar efforts in his *manteqa* (indirect exposure).

Respondents were also asked “how often do you encounter foreign forces in the area where you live?” This question, which was not asked about the Taliban for security reasons, aimed to control for prior level of interaction with ISAF forces. Possible answers ranged from “daily” and “several times a week” to “several times a month” and “never.”

Figure 12 presents mosaic plots summarizing four key questions (two for each combatant) about exposure to violence: whether the respondent had experienced harm from Taliban and ISAF-initiated violence and whether the responsible combatant subsequently approached harmed individuals (see Section 2.3).

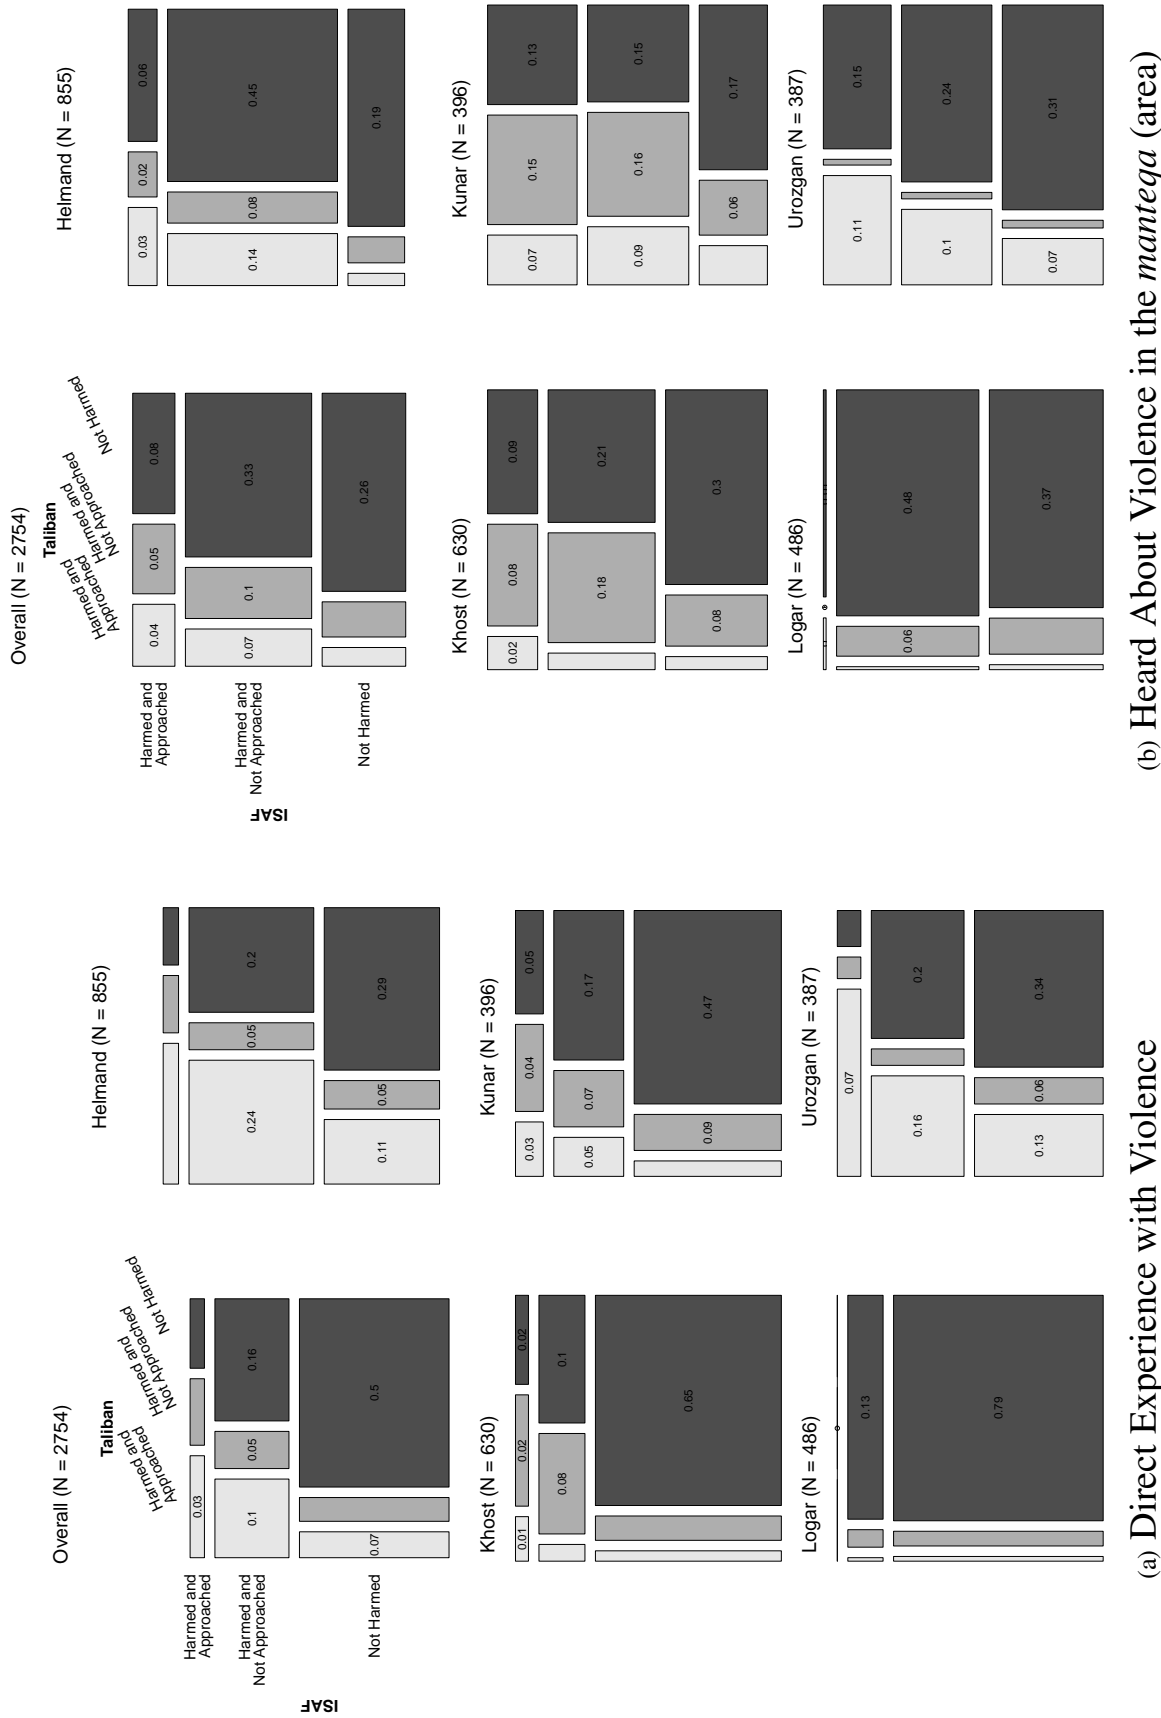

Figure 12: Responses to the Questions about Harm from Taliban- and ISAF- Inflicted Violence and Whether Victims were Subsequently “Approached” by Combatants. Mosaic plots depict the overall and inter-province distributions of responses at the self/family (left two columns) and *manteqa* (right two columns) levels. In each plot, the area of a rectangle is proportional to the number of respondents who answered those four questions in a specific way. The number in each rectangle represents the proportion of the same of the corresponding subgroup. “Don’t Know” and “Refuse to Answer” were dropped as they accounted for at most 2% of the sample.

Plots were created for direct exposure to violence (Figure 12(a)) and indirect exposure in the *manteqa* (Figure 12(b)) for the sample average and for each province. In each mosaic plot, the rectangle's area is proportional to the number of respondents who answered a specific combination of these four questions. For example, the plot in the upper left corner illustrates the overall distribution for direct exposure to violence; the largest rectangle depicts those that did not experience harm by either the Taliban or ISAF and who were, as a consequence, not approached.

Province-level variation is broadly consistent with the pattern of violence outlined in Section 2.2. Helmand is associated with the highest recorded levels of violence from individual and *manteqa* level self-reports (right corner plots of each subfigure) and from the CIDNE data, for example. Logar, by contrast, is associated with the lowest levels of self-reported victimization (left bottom corner plot of Figure 12(a)) and CIDNE data.

A.5 Coefficient Estimates of the Full Models
